## **Exercise sheet 8: Donsker's invariance principle** (v2)

## **Exercise 1** — *Recurrence and Donsker.*

You know that almost surely the random walk on  $\mathbb{Z}^2$  visits 0 infinitely often. Is it the case for the bidimensional Brownian motion? What does Donsker's invariance principle tell us here?

## **Exercise 2** — *Skorokhod's embedding.*

Let X be a centered random variable with variance 1.

- (1) Argue for the existence of a sequence of random times  $T_k$  such that  $(T_k T_{k-1})_k$  is an i.i.d. sequence of mean 1 and  $(S_k)_k = (B_{T_k})_k$  is a random walk whose increments are distributed like X. Define  $(\widetilde{S}_t^n)_t = (\frac{S_{nt}}{\sqrt{n}})_t$  its (properly interpolated) rescaled version.
- (2) Let  $\phi_n(t) = n^{-1}T_{\lfloor nt \rfloor}$ . Show that almost surely this random function converges uniformly on every compact to the identity  $\mathbb{R}_+ \to \mathbb{R}_+$ .
- (3) Show that  $\widetilde{S}^n = (t \mapsto n^{-1/2} B_{nt}) \circ \phi_n$  at points that are multiples of 1/n. Deduce that  $\|\widetilde{S}^n (t \mapsto n^{-1/2} B_{nt})\|_{[0,T]}$  goes to 0 in probability for every T.
- (4) Deduce Donsker's theorem.

## **Exercise 3** — Donsker's theorem for bridges.

In this exercise, let b(n, p, k) denote the probability that a binomial of parameters (n, p) equals k, and f denote the standard Gaussian density. We will make use of the following *local limit theorem*, which is a refinement of the central limit theorem.

**Theorem.** (De Moivre–Laplace) As  $n \to \infty$ ,

$$\sup_{k\in\mathbb{Z}}\left|\sqrt{p(1-p)n}b(n,p,k) - f\left(\frac{k-np}{\sqrt{p(1-p)n}}\right)\right| = o(n^{-1/2}).$$

Recall (a few sessions back) that the Brownian bridge  $\beta$  (from 0 to 0) has the following property: for every integrable function H and  $\epsilon > 0$ ,

$$\mathbb{E}\left[H(\beta_{|[0,1-\epsilon]})\right] = \mathbb{E}\left[H(B_{|[0,1-\epsilon]})\frac{\epsilon^{-1/2}f(B_{1-\epsilon})}{f(0)}\right].$$

Define the simple random walk S and its interpolated and rescaled version  $\tilde{S}^n$ . Our goal is to show that the distribution of  $\tilde{S}^{2n}$  given that it is a bridge (i.e.  $\tilde{S}_{2n} = 0$ ), converges to that of  $\beta$  as  $n \to \infty$ .

(1) Let H be a bounded continuous or positive measurable function. Fix  $n \ge 1$  and  $k_n \le n-1$ . Show that

$$\mathbb{E}[H(\widetilde{S}^{2n}_{|[0,k_n/n]}) \mid \widetilde{S}_{2n} = 0] = \mathbb{E}\left[H(\widetilde{S}^{2n}_{|[0,k_n/n]})\frac{b(\frac{1}{2},2n-2k_n,n-k_n+\frac{\sqrt{2n}}{2}\widetilde{S}_{k/n})}{b(\frac{1}{2},2n,n)}\right]$$

- (2) Suppose that  $k_n/n \to 1 \epsilon$ . Denote by  $A_n$  the fraction appearing in the righthand side. Show that  $A_n$  is bounded by  $b(\frac{1}{2}, 2n - 2k_n, n - k_n)/b(\frac{1}{2}, 2n, n)$ , which (deterministic) bound converges to a constant. Deduce that the tightness criterion (the bound on  $\mathbb{E}[|\widetilde{S}_t^{2n} - \widetilde{S}_s^{2n}|^4]$ ) that applies to  $\widetilde{S}^{2n}$  still applies to the conditioned version.
- (3) Show that there exists a deterministic  $o(n^{-1/2})$  such that almost surely we have  $\left|A_n \frac{\epsilon^{-1/2} f(\tilde{S}_{k/n}^{2n})}{f(0)}\right| = o(n^{-1/2})$ . Deduce that all finite-dimensional marginals of  $\tilde{S}^{2n}$  given  $\tilde{S}^{2n} = 0$  converge to that of the Brownian bridge.
- (4) Conclude.
