9.3

Objectives

- To describe the benefits of a virtual memory system
- To explain the concepts of demand paging, page-replacement algorithms, and allocation of page frames
- To discuss the principle of the working-set model

Operating System Concepts – 7th Edition, Feb 22, 2005

Background

- Memory management (chap 8)
 - instruction being executed must be in physical memory
 - Place the entire logical memory in physical memory
 - Dynamic loading may help
 - Special precaution / extra work
 - Seems necessary & reasonable
 - Unfortunate
 - Ilmits the size of a program
- Entire program is not needed in many cases:
 - Code for unusual error condition
 - Array /lists allocate more memory than needed...
 - Some option/features rarely used

Operating System Concepts - 7th Edition, Feb 22, 2005

9.5

Background (cont)

- Benefits
 - No constraint by the limit of the physical memory
 - More programs could be run at the same time
 - Increase in CPU utilization, Throughput
 - > Same response time or turnaround
 - Less I/O to load/swap each user program / run faster

Operating System Concepts – 7th Edition, Feb 22, 2005

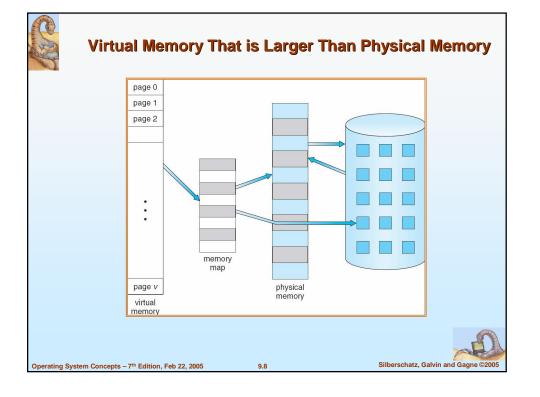

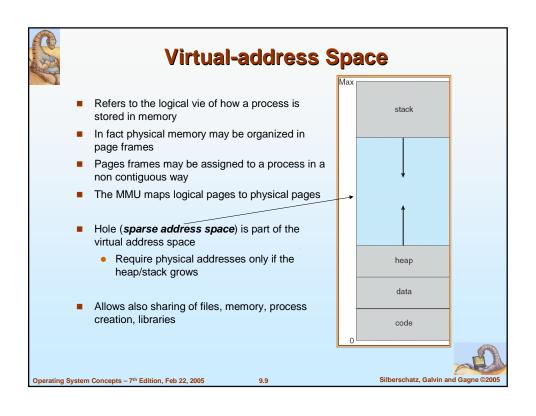

Background (cont)

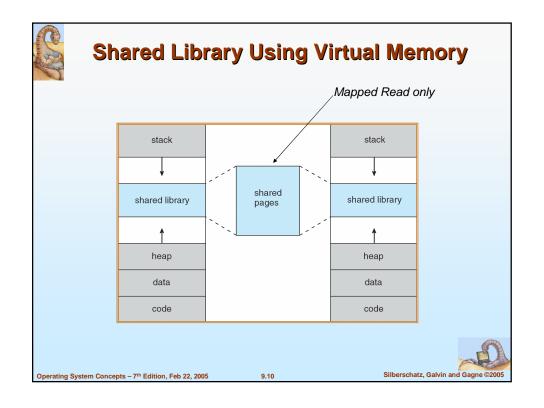

- Virtual memory separation of user logical memory from physical memory.
 - Only part of the program needs to be in memory for execution
 - Logical address space can therefore be much larger than physical address space
 - Programming task much more easier
 - Allows address spaces to be shared by several processes
 - Allows for more efficient process creation
- Virtual memory can be implemented via:
 - Demand paging
 - Demand segmentation

Operating System Concepts – 7th Edition, Feb 22, 2005

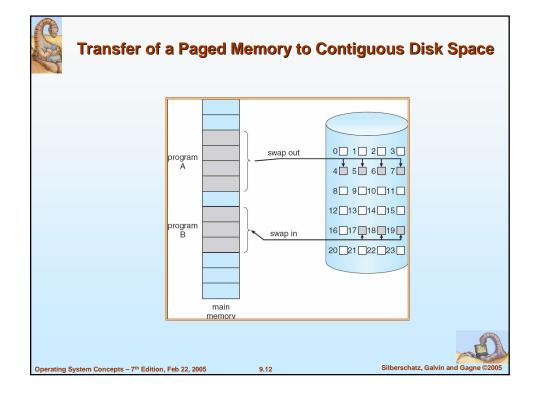

Demand Paging

- Bring a page into memory only when it is needed
 - Less I/O needed
 - Less memory needed
 - Faster response
 - More users
- Page is needed ⇒ reference to it
 - invalid reference ⇒ abort
 - not-in-memory ⇒ bring to memory
- Lazy swapper never swaps a page into memory unless page will be needed
 - Swapper that deals with pages is a pager

Operating System Concepts – 7th Edition, Feb 22, 2005

0 11

Basic concept

- Pager "guesses" which pages will be used before the process is swapped out again
- Need support to distinguish between the pages that are
 - In memory
 - On the disk

Operating System Concepts – 7th Edition, Feb 22, 2005

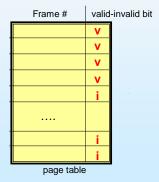

0.42

Valid-Invalid Bit

- With each page table entry a valid–invalid bit is associated (v ⇒ in-memory, i ⇒ not-in-memory)
- Initially valid—invalid bit is set to i on all entries
- Example of a page table snapshot:

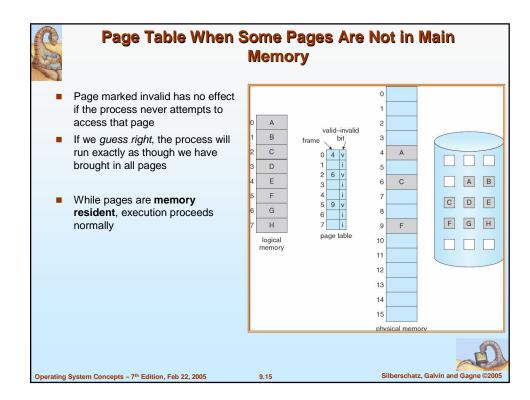

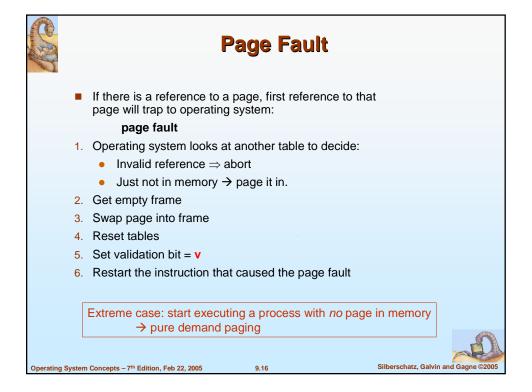

■ During address translation, if valid–invalid bit in page table entry is I ⇒ page fault

Performance of Demand Paging

- Page Fault Rate $0 \le p \le 1.0$
 - if p = 0 no page faults
 - if p = 1, every reference is a fault
- Effective Access Time (EAT)

```
EAT = (1 - p) x memory access
+ p (page fault overhead
+ swap page out
+ swap page in
+ restart overhead
```

Operating System Concepts – 7th Edition, Feb 22, 2005

9.19

Demand Paging Example

- Memory access time = 200 nanoseconds
- Average page-fault service time = 8 milliseconds
- EAT = $(1 p) \times 200 + p \times (8 \text{ milliseconds})$ = $(1 - p \times 200 + p \times 8,000,000)$ = $200 + p \times 7,999,800$
- If one access out of 1,000 causes a page fault, then EAT = 8.2 microseconds.

2711 = 0.2 111101000001140.

This is a slowdown by a factor of 40!!

- Performance degradation < 10%
 - P < 0.0000025

Operating System Concepts – 7th Edition, Feb 22, 2005

Process Creation

- Virtual memory allows other benefits during process creation:
 - Copy-on-Write
 - Memory-Mapped Files (later)
- fork() system call creates a child process as a duplicate of its parent
 - Many child call exec() system call immediately after creation
 - Unnecessary code copy... waste of time

Operating System Concepts – 7th Edition, Feb 22, 2005

0.21

Copy-on-Write

 Copy-on-Write (COW) allows both parent and child processes to initially share the same pages in memory

If either process modifies a shared page, only then is the page copied

- Only pages that can be modified are marked CoW (not the code)
- COW allows more efficient process creation as only modified pages are copied
- Free pages are allocated from a **pool** of zeroed-out pages

Operating System Concepts – 7th Edition, Feb 22, 2005

What happens if there is no free frame?

- Page replacement find some page in memory, but not really in use, swap it out
 - algorithm
 - performance want an algorithm which will result in minimum number of page faults
- Same page may be brought into memory several times

Operating System Concepts – 7th Edition, Feb 22, 2005

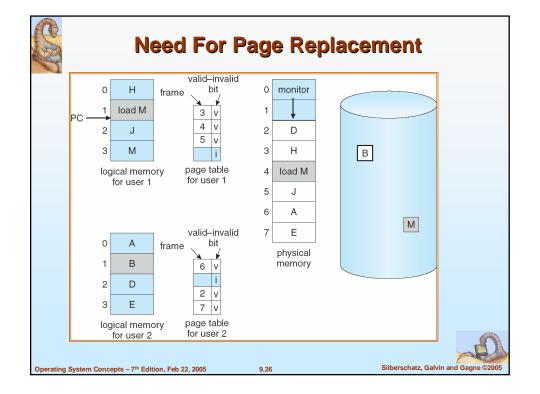

Page Replacement

- Prevent over-allocation of memory by modifying page-fault service routine to include page replacement
- Use modify (dirty) bit to reduce overhead of page transfers only modified pages are written to disk
- Page replacement completes separation between logical memory and physical memory – large virtual memory can be provided on a smaller physical memory
- Need
 - Frame allocation algorithm
 - Page replacement algorithm

Operating System Concepts - 7th Edition, Feb 22, 2005

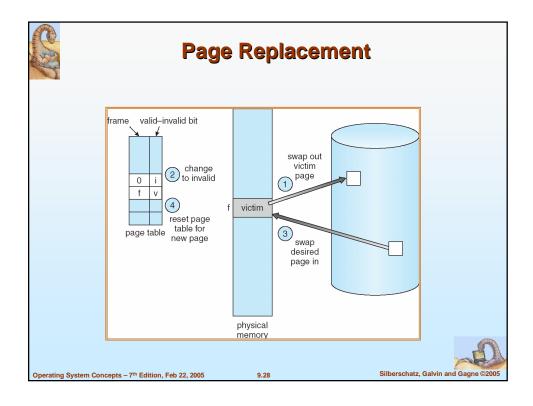

Basic Page Replacement

- 1. Find the location of the desired page on disk
- 2. Find a free frame:
 - If there is a free frame, use it
 - If there is no free frame, use a page replacement algorithm to select a **victim** frame
- 3. Bring the desired page into the (newly) free frame; update the page and frame tables
- 4. Restart the process

Operating System Concepts – 7th Edition, Feb 22, 2005

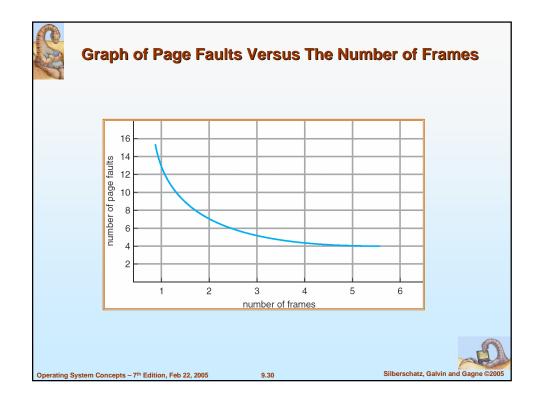

Page Replacement Algorithms

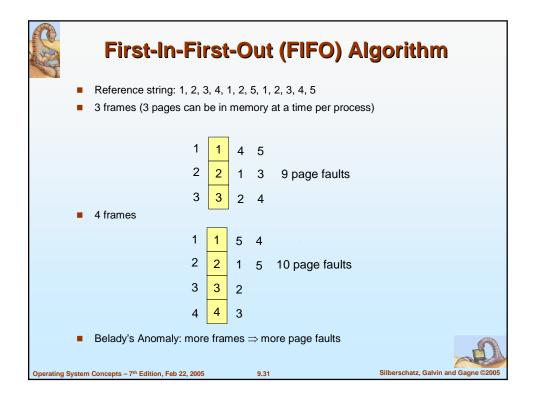

- Want lowest page-fault rate
- Evaluate algorithm by running it on a particular string of memory references (reference string) and computing the number of page faults on that string
- In all our examples, the reference string is

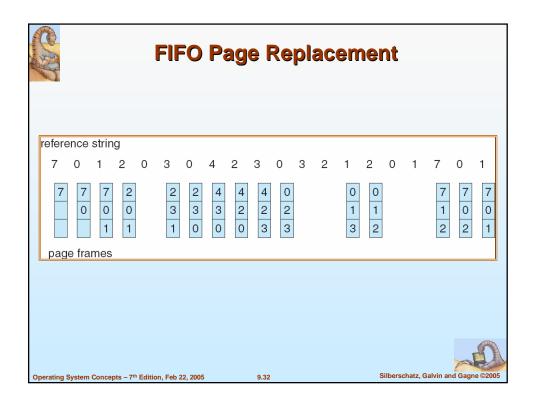

1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5

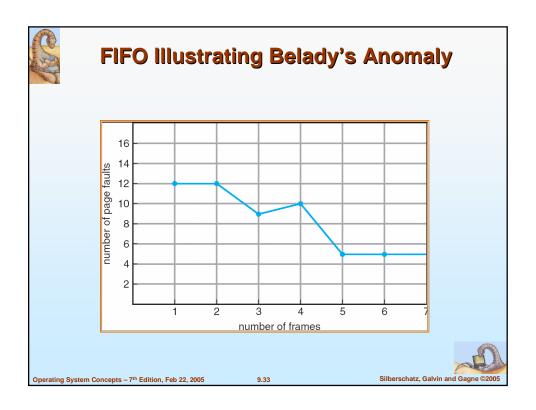

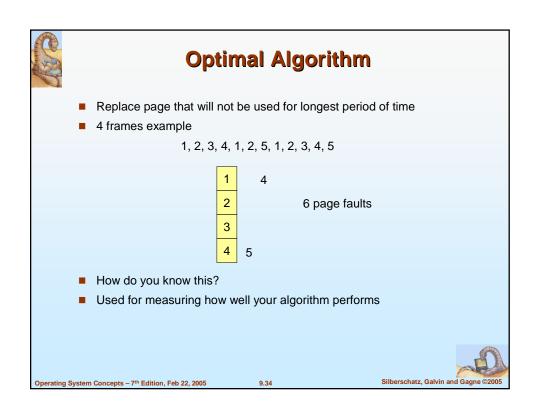

Operating System Concepts - 7th Edition, Feb 22, 2005

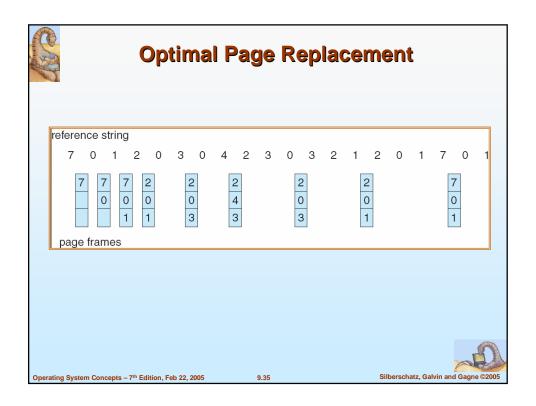

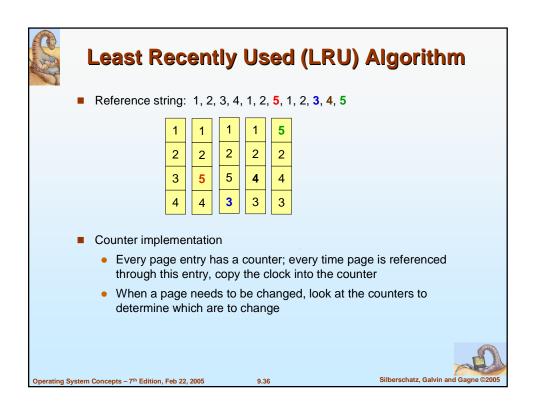

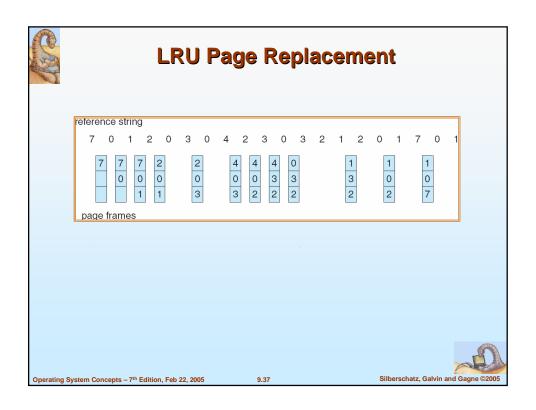

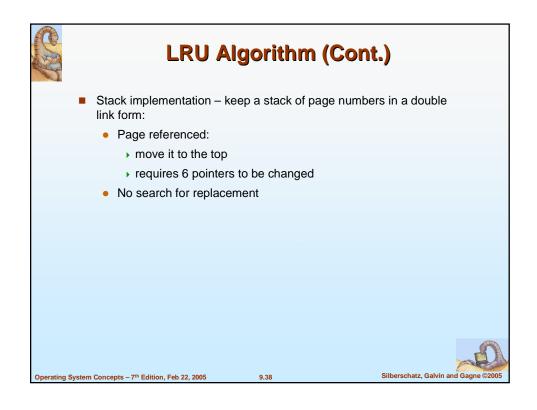

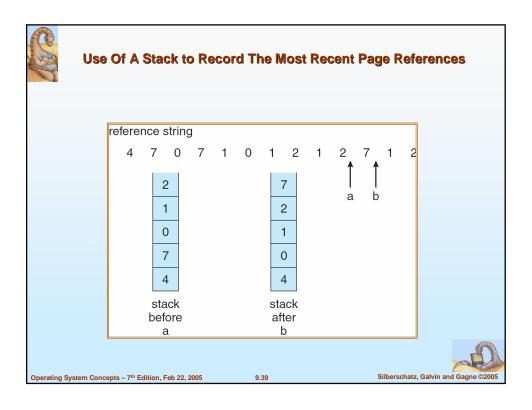

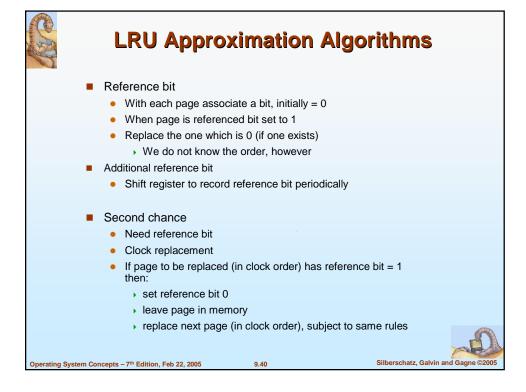

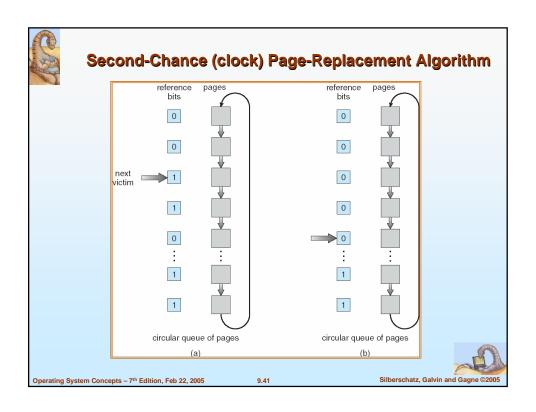

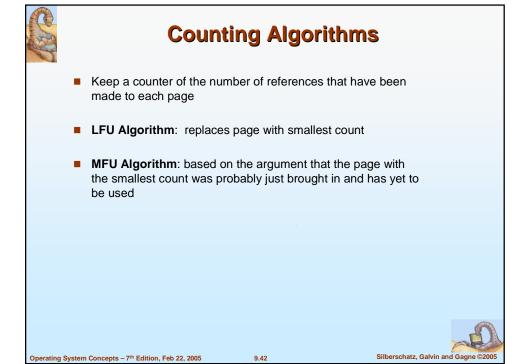

Allocation of Frames

- How do we allocate the fixed amount of free memory among the various processes ?
- Each process needs *minimum* number of pages
- Example: IBM 370 6 pages to handle SS MOVE instruction:
 - instruction is 6 bytes, might span 2 pages
 - 2 pages to handle from
 - 2 pages to handle to
- Two major allocation schemes
 - fixed allocation
 - priority allocation

Operating System Concepts – 7th Edition, Feb 22, 2005

0.41

Fixed Allocation

- Equal allocation For example, if there are 100 frames and 5 processes, give each process 20 frames.
- Proportional allocation Allocate according to the size of process
 - $-s_i = \text{size of process } p_i$
 - $-S = \sum S_i$
 - -m = total number of frames

$$-a_i = \text{allocation for } p_i = \frac{s_i}{S} \times m$$

$$m = 64$$

$$s_i = 10$$

$$s_2 = 127$$

$$a_1 = \frac{10}{137} \times 64 \approx 5$$

$$a_2 = \frac{127}{137} \times 64 \approx 59$$

Operating System Concepts – 7th Edition, Feb 22, 2005

Priority Allocation

- Use a proportional allocation scheme using priorities rather than size
- If process *P_i* generates a page fault,
 - select for replacement one of its frames
 - select for replacement a frame from a process with lower priority number

Operating System Concepts – 7th Edition, Feb 22, 2005

0.45

Global vs. Local Allocation

- Global replacement process selects a replacement frame from the set of all frames; one process can take a frame from another
- Local replacement each process selects from only its own set of allocated frames
- With a global replacement, a process can not control its own page fault behavior

Operating System Concepts – 7th Edition, Feb 22, 2005

Thrashing

- If a process does not have "enough" pages, the page-fault rate is very high. This leads to:
 - low CPU utilization
 - operating system thinks that it needs to increase the degree of multiprogramming
 - another process added to the system
- Thrashing = a process is busy swapping pages in and out

Operating System Concepts – 7th Edition, Feb 22, 2005

Operating System Concepts – 7th Edition, Feb 22, 2005

0.47

Thrashing (Cont.) degree of multiprogramming Limit the trashing by using local replacement algorithm / priority replacement → process trashing → in paging queue most of the time → access time will increase We need to provide a process with as many frames as it needs How do we know how many frames it "needs"?

Demand Paging and Thrashing

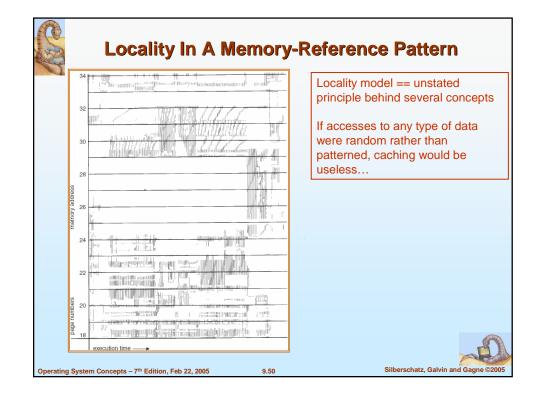

- Why does demand paging work? Locality model
 - Process migrates from one locality to another
 - Localities may overlap
- Allocate enough frames to a process to accommodate its current locality
- Why does thrashing occur?
 Σ size of locality > total memory size

Operating System Concepts - 7th Edition, Feb 22, 2005

lberschatz, Galvin and Gagne ©2005

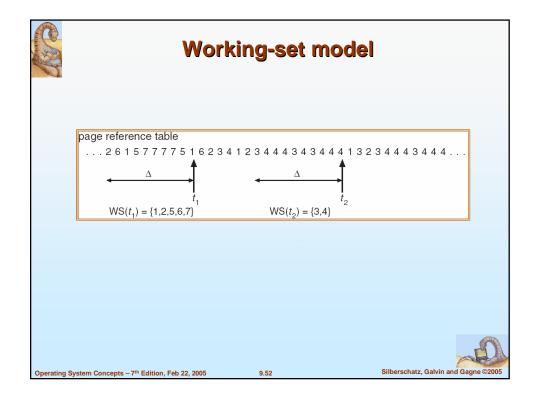

Working-Set Model

- ∆ = working-set window = a fixed number of page references Example: 10,000 instruction
- WSS_i (working set of Process P_i) = total number of pages referenced in the most recent ∆ (varies in time)
 - if Δ too small will not encompass entire locality
 - if Δ too large will encompass several localities
 - if $\Delta = \infty \Rightarrow$ will encompass entire program
- $D = \Sigma$ WSS_i = total demand frames
- if $D > m \Rightarrow$ Thrashing
- Policy if *D* > m, then suspend one of the processes

Operating System Concepts – 7th Edition, Feb 22, 2005

Keeping Track of the Working Set

- Approximate with interval timer + a reference bit
- Example: $\Delta = 10,000$
 - Timer interrupts after every 5000 time units
 - Keep in memory 2 bits for each page
 - Whenever a timer interrupts copy and sets the values of all reference bits to 0
 - If one of the bits in memory = $1 \Rightarrow$ page in working set
- Why is this not completely accurate?
- Improvement = 10 bits and interrupt every 1000 time units

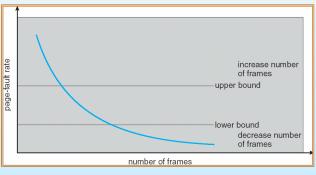

Operating System Concepts – 7th Edition, Feb 22, 2005

9.53

Page-Fault Frequency Scheme

- Establish "acceptable" page-fault rate
 - If actual rate too low, process loses frame
 - If actual rate too high, process gains frame

Operating System Concepts – 7th Edition, Feb 22, 2005

Memory-Mapped Files

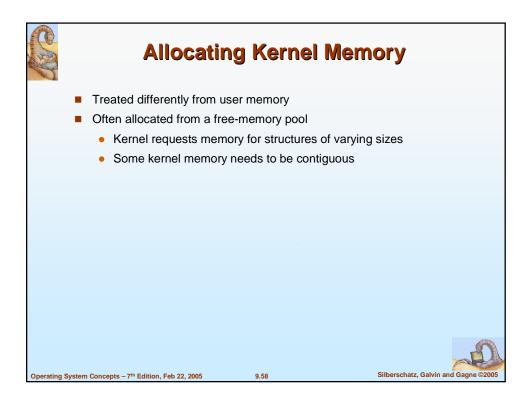

- Memory-mapped file I/O allows file I/O to be treated as routine memory access by mapping a disk block to a page in memory
- A file is initially read using demand paging. A page-sized portion of the file is read from the file system into a physical page. Subsequent reads/writes to/from the file are treated as ordinary memory accesses.
- Simplifies file access by treating file I/O through memory rather than read() write() system calls
- Also allows several processes to map the same file allowing the pages in memory to be shared

Operating System Concepts – 7th Edition, Feb 22, 2005

Buddy System

- Allocates memory from fixed-size segment consisting of physicallycontiguous pages
- Memory allocated using **power-of-2 allocator**
 - Satisfies requests in units sized as power of 2
 - Request rounded up to next highest power of 2
 - When smaller allocation needed than is available, current chunk split into two buddies of next-lower power of 2
 - Continue until appropriate sized chunk available

Slab Allocator

- Alternate strategy
- Slab is one or more physically contiguous pages
- Cache consists of one or more slabs
- Single cache for each unique kernel data structure
 - Each cache filled with objects instantiations of the data structure
- When cache created, filled with objects marked as free
- When structures stored, objects marked as used
- If slab is full of used objects, next object allocated from empty slab
 - If no empty slabs, new slab allocated
- Benefits include no fragmentation, fast memory request satisfaction

Operating System Concepts – 7th Edition, Feb 22, 2005

Other Issues -- Prepaging

- Prepaging
 - To reduce the large number of page faults that occurs at process startup
 - Prepage all or some of the pages a process will need, before they are referenced
 - But if prepaged pages are unused, I/O and memory was wasted
 - Assume s pages are prepaged and α of the pages is used
 - \blacktriangleright Is cost of s * α save pages faults > or < than the cost of prepaging
 - $s * (1-\alpha)$ unnecessary pages?
 - → α near zero ⇒ prepaging loses

Operating System Concepts - 7th Edition, Feb 22, 2005

0.61

Other Issues - Page Size

- Page size selection must take into consideration:
 - fragmentation
 - table size
 - I/O overhead
 - locality

Operating System Concepts – 7th Edition, Feb 22, 2005

Other Issues - TLB Reach

- TLB Reach The amount of memory accessible from the TLB
- TLB Reach = (TLB Size) X (Page Size)
- Ideally, the working set of each process is stored in the TLB
 - Otherwise there is a high degree of page faults
- Increase the Page Size
 - This may lead to an increase in fragmentation as not all applications require a large page size
- Provide Multiple Page Sizes
 - This allows applications that require larger page sizes the opportunity to use them without an increase in fragmentation

Operating System Concepts - 7th Edition, Feb 22, 2005

9.65

Other Issues - Program Structure

- Program structure
 - Int[128,128] data;
 - · Each row is stored in one page
 - Program 1

 $128 \times 128 = 16,384$ page faults

Program 2

```
for (i = 0; i < 128; i++)

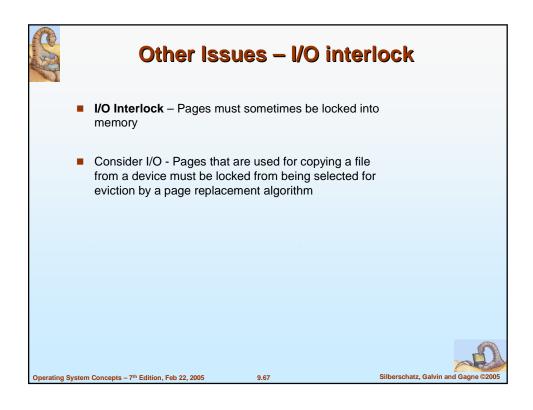

for (j = 0; j < 128; j++)

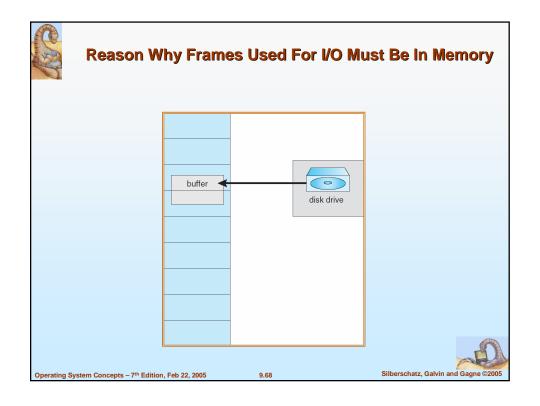

data[i,j] = 0;
```

128 page faults

Operating System Concepts – 7th Edition, Feb 22, 2005

Operating System Examples

- Windows XP
- Solaris

Operating System Concepts – 7th Edition, Feb 22, 2005

9.69

Windows XP

- Uses demand paging with clustering. Clustering brings in pages surrounding the faulting page.
- Processes are assigned working set minimum and working set maximum
- Working set minimum is the minimum number of pages the process is guaranteed to have in memory
- A process may be assigned as many pages up to its working set maximum
- When the amount of free memory in the system falls below a threshold, automatic working set trimming is performed to restore the amount of free memory
- Working set trimming removes pages from processes that have pages in excess of their working set minimum

Operating System Concepts – 7th Edition, Feb 22, 2005

Solaris

- Maintains a list of free pages to assign faulting processes
- Lotsfree threshold parameter (amount of free memory) to begin paging
- Desfree threshold parameter to increasing paging
- Minfree threshold parameter to being swapping
- Paging is performed by pageout process
- Pageout scans pages using modified clock algorithm
- Scanrate is the rate at which pages are scanned. This ranges from slowscan to fastscan
- Pageout is called more frequently depending upon the amount of free memory available
