

# WSim et WSNNet : outils de simulation pour le développement d'application de réseaux de capteurs

Antoine Fraboulet   Guillaume Chelius   Éric Fleury

CITI Laboratory

INSA Lyon

INRIA ARES Project

# Utilisation des outils dans la conception

# Outils

## WSim : simulation de la plate-forme matérielle

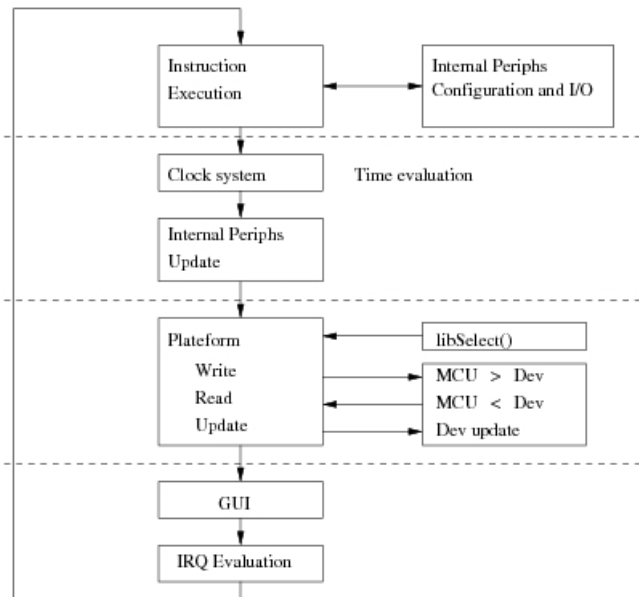

- Simulation précise en temps
- Plateforme complète
- Interaction avec WSNNet pour la simulation du réseau
- Utilise le binaire final de l'application

## WSNet : Simulateur de réseau radio

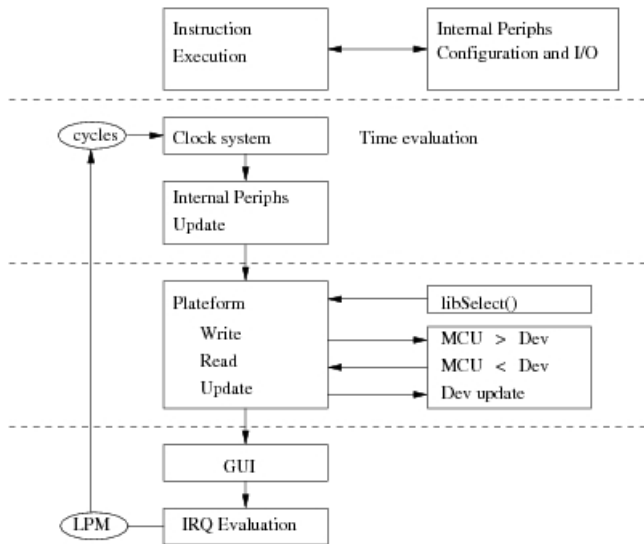

- Simulation événementielle
- Utilisation du simulateur pour les couches physique et radio
- Frontend UDP/IP (multicast)

## WSNet + WSim : complete distributed system simulation

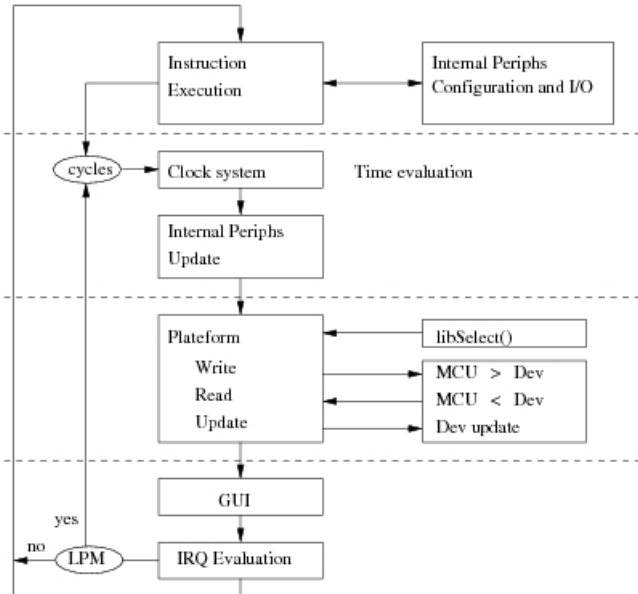

# WSim : boucle de simulation

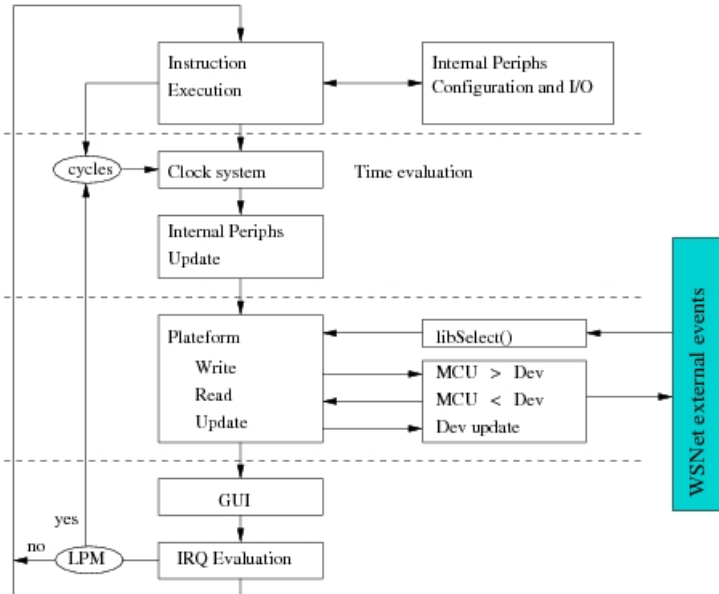

# WSim : boucle de simulation

# WSim : boucle de simulation

# WSim : boucle de simulation

# Simulation précise à l'instruction

## Traces générées

- Interruptions / activité
- Mode de veille
- Communications

## Activité des nœuds

- Événements radio
- Analyse hors-ligne

## Evaluation de performance

- Instructions
- Emprunte Mémoire
- *Consommation*

# Gestion des fréquences des micro-contrôleurs

## Clock modules simulation

- Fréquences variables
- Dérive d'horloge
- Estimation de la puissance et énergie

## Simulation du système d'horloge

# Debug

The image shows a debugger window with the following components:

- Source Code:** A C++ code snippet with a highlighted line: `printf("Am I back? %s\n", mystr);` at line 27. The code includes headers for `string` and `string_view`, and defines a `main` function that prints "Am I back?", calls `std::string_view mystr("Am I back?");`, and then loops to print `mystr` five times.
- Registers:** A table showing the state of CPU registers. The `EAX` register contains the value `00000000`.
- Local Variables:** A table showing the state of local variables. The `mystr` variable is shown with a value of `Am I back?`.
- Console:** A terminal window at the bottom left showing the output of the program: `Am I back?` followed by five lines of `Am I back?`.

# Performance evaluation of wireless Networks

## Wireless multi-hop networks (adhoc/sensor/mesh) :

- Large number of wireless nodes
- Self-organizing network
- Unreliable radio link
- Application-specific constraints : mobility, energy, etc.

## Performance evaluation of wireless systems :

- Analytical models (stochastic geometry, percolation, random processes, Markov chains)
- One-shot experiments or setting-up of large scale testbeds
- **Simulation is generally the most convenient performance evaluation methodology**

# Simulation of wireless networks : bestiary

A wide range of alternatives : NS-2, NS-3, Glo- MoSim, JiST/SWANS, GTSNetS, OPNET, OMNeT++, J-Sim, QualNet, *etc.*

*Same global architecture → discrete time event-driven simulation*

But differs in many aspects :

- implementation :
  - *user interface* : simulation scripting, simulation monitoring
  - *developer interface* : programming language, development integration
  - *simulator internal* : mobility management, event management
- modeling :
  - node architecture
  - radio medium properties
  - environment

## Simulation of wireless networks : bestiary

	Jist/Swan	GTNets	GlomoSim	NS-2
Licence	Academic	GPL	Academic	GPL
Language / API	Java	C++	C/C++	C/TCL
Area dimension	2D	2D	2D	2D
Space partitioning	Hierarchical binning	Flat	Flat	Flat/Grid
Event queue	Heap	B tree	Splay tree	List

## E.g. mobility management

*What are the nodes  $y$  such that  $d(x, y) < l$ ?*

Node position management : flat / grid / dbtree/ quadtree architectures.

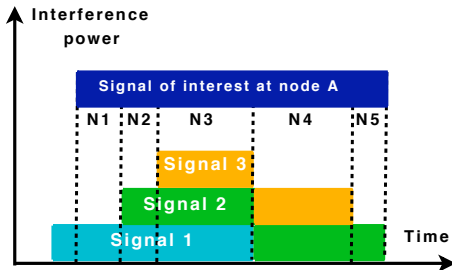

*When to update node locations?*

- *when needed* : event-driven
- *periodically* : time-driven
- *hybrid* :  $\max(\text{time}, \text{event})$ -driven

## E.g. radio modeling

SINR computation vary from a simulator to another :

- **strongest** :  $SINR_A = \frac{N_A}{N_3}$
- **cumulative** :  $SINR_A = \frac{N_A}{N_5}$
- **adaptative** :  $SINR_{A_1} = \frac{N_A}{N_1}$ ,  $SINR_{A_2} = \frac{N_A}{N_2} \dots$

## E.g. radio modeling

Models	NS2	GloMoSim	JiST/SWANS	GTSNetS	WSNet
<b>Pathloss</b>	freespace tworay	freespace tworay	freespace tworay	freespace tworay	freespace tworay
<b>Shadowing Fading</b>	log-normal rician,rayleigh	log-normal rician,rayleigh	- rician,rayleigh,...	- -	log-normal rician,rayleigh
<b>Radio link Modulation</b>	threshold -	threshold,BER BPSK,QPSK	threshold,BER BPSK	threshold -	threshold,BER BPSK,OQPSK,...
<b>Interference SINR</b>	limited strongest signal	limited adaptive	limited cumulative	limited strongest signal	limited,full adaptive cumulative

Interference modeling is the point where current simulators differ the most largely.

Other aspects not addressed here : capture effect, propagation delay, adjacent-channel interference, antenna radiation patterns, *etc.*

# Simulation of wireless networks

Numerous simulators have been proposed. However :

- Optimizations are made to cope with the complexity of wireless communication
- The PHY-modeling accuracy varies from one simulator to another
- The behavior of protocols may radically differ from one simulator to another

Motivation :

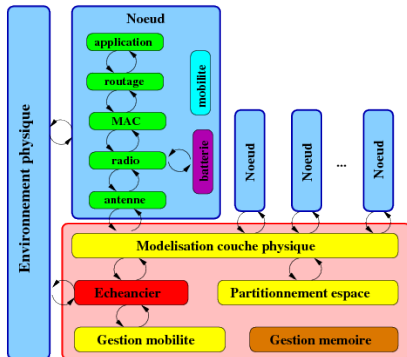

- In-depth analysis of the modeling of wireless networks
- Comparative study for existing simulators
- The impact of the PHY-modeling on the simulation results
- The impact of the protocol parameters on the simulation results

# WSNet

WSNet architecture :

- simulator core : event queue, mobility management, packet queue, *etc.*
- dynamic libraries : implement node / medium / environment models.

A simulation must specify which models are to be used.

# PHY-layer modeling in WSNet

In analytical studies as in simulation, the unit disk model has been widely used :

- Strong assumptions : time stationarity, independence, symmetry, switched link, isotropy, *etc.*
- Unrealistic PHY model : radio range is constant, radio link is switched, interference free network

Three main steps towards a realistic radio medium modeling :

- Radio range modeling
- Radio link modeling
- Interference modeling

## WSNet : radio range modeling (1/3)

The range of a radio system is based upon the definition of a *SNR* threshold noted  $\bar{\gamma}_{ij}$

If the system is interference free, the range is constant and the radio link  $l_{ij}$  is defined by :

$$l_{ij} : \Omega^2 \mapsto B = \{0, 1\}$$

$$(x_i, x_j) \mapsto l(x_i, x_j) = \begin{cases} 1 & \text{if } \bar{\gamma}_{ij} \geq \bar{\gamma}_{lim} \\ 0 & \text{else} \end{cases}$$

$$\text{where : } \bar{\gamma}_{ij} = h_{ij} \cdot \frac{P_i}{N_j}$$

$h_{ij}$  depends on several physical phenomena (*i.e.*, pathloss, fading, shadowing).

# WSNet : radio range modeling (2/3)

## pathloss

(signal attenuation in fct. of the distance)

e.g. : freespace, tworay

## shadowing

(slow signal fluctuation due to obstacles)

e.g. : log-normal

## fading

(fast signal fluctuation due to multipath)

e.g. : rician, rayleigh

## WSNet : radio range modeling (3/3)

pathloss + shadowing + fading

The radio link  $l_{ij}$  is then defined by :

$$l_{ij} : \Omega^2 \mapsto B = \{0, 1\}$$

$$(x_i, x_j) \mapsto l(x_i, x_j) = \begin{cases} 1 & \text{if } \bar{\gamma}_{ij} = h_{ij} \cdot \frac{P_i}{N_j} \\ 0 & \text{else} \end{cases}$$

where :

$$h_{ij} = \mathbf{g}_{ij} \cdot \mathbf{s}_{ij} \cdot \mathbf{f}_{ij}(t) \cdot \mathbf{g}_i(\theta_{ij}, \phi_{ij}) \cdot \mathbf{g}_j(\theta_{ji}, \phi_{ji})$$

## WSNet : radio link modeling

A more realistic link modeling is to substitute the *SNR* threshold by a **packet error rate** (*PER*) which depends on the **bit error rate** (*BER*). This *BER* is computed according to the *SNR* and the **modulation scheme**.

- The probability to receive a bit :  $BER = f_{modulation}(SNR)$
- The probability to receive a packet of  $N$  bits :  $PER = 1 - (1 - BER)^N$

# WSNet : interference modeling

Inteferece is a major limiting factor for wireless communication systems

The *SNR* is replaced by a signal to interference plus noise ratio (*SINR*) defined in the shotnoise model by :

$$\bar{\gamma}_{ij} = h_{ij} \cdot \frac{P_i}{N_j + \sum_{k \neq i,j} \alpha_{ik} \cdot h_{kj} \cdot P_k}$$

Numerous simulators **limit the range** at which a signal can propagate and thus can interfere. This privileges the scalability at the cost of accuracy.

# Impact of radio range models

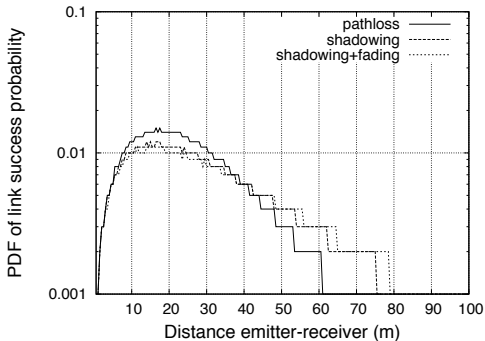

Fig.: Impact of the radio range modeling on the link success probability (without interference modeling).

# Impact of radio link models

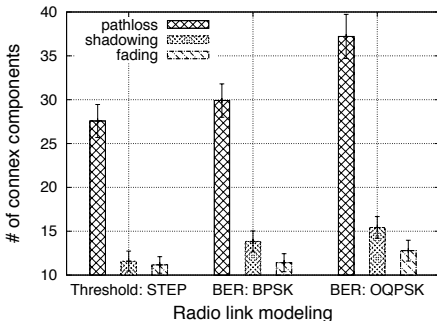

Fig.: Impact of the radio link modeling on the average number of connex components (without interference modeling).

# Impact of interference

Fig.: Impact of the radio range on the link success probability (with interference modeling).

# WSNet : environment

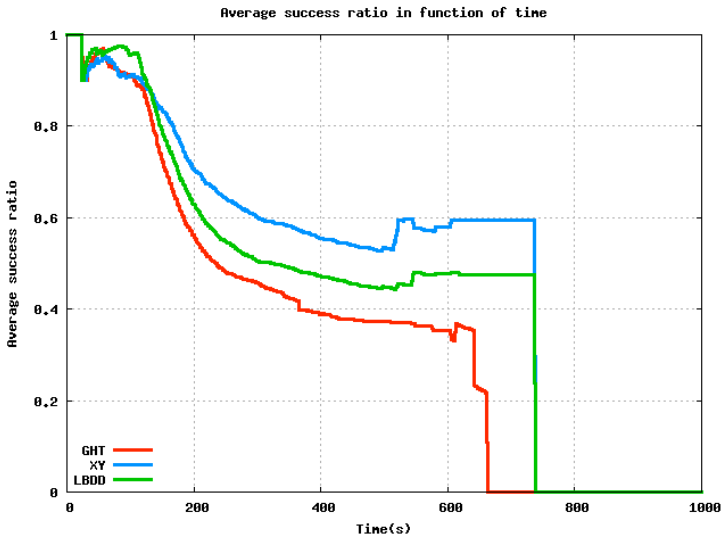

Environment simulation :

- *Environment* → *node* interactions : sensing, node death
- *Node* → *environment* interactions : actuators

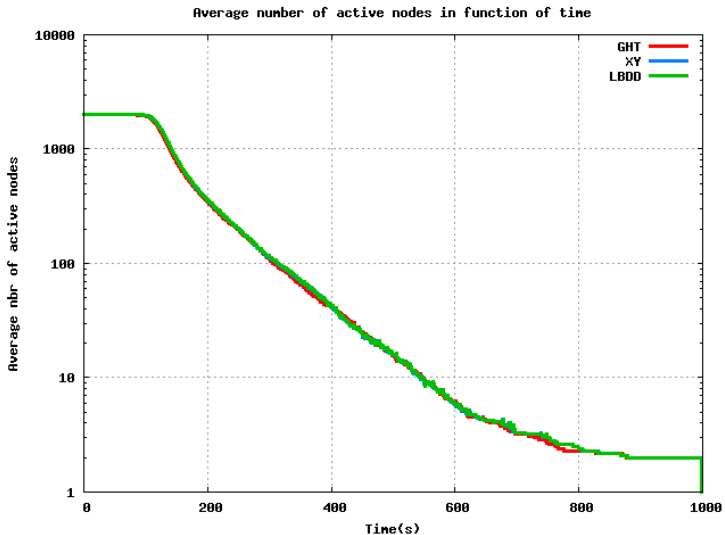

# WSNet : network lifetime

A network does not die when the first node dies.

# WSNet : network lifetime

A network does not die when the first node dies.

## The future of WSNets...

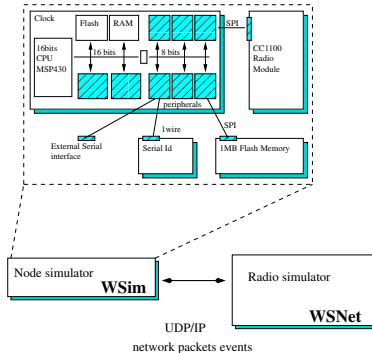

WSNet-3 is now under development :

- *High Level Languages* for model development (e.g. Ruby, Python)
- *Packet typing* : easier protocol developments, better result synthesis.
- *Rethinking the medium model* : UWB support? better support of multi-channels, MIMO systems, etc.
- *Rethinking the environment support*

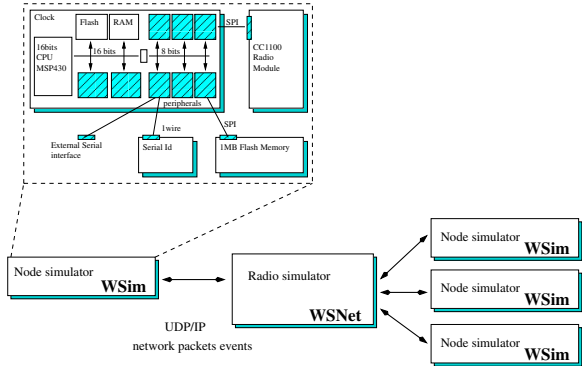

Anyway, at that time, please go and refer to :

# Simulation mixte

# Simulation mixte

# Simulation mixte

## Simulation mixte

- La simulation distribuée permet de faire du pas à pas sur l'application de façon globale
- Les mesures de performances locales associées aux communications permettent de faire ressortir le comportement de l'application complète.
- La mesure de consommation en analyse hors-ligne permet de mesurer les divers compromis existant dans l'architecture entre calcul et communication.
- Des changements d'annotation de consommation permettent de détecter les composants du système qui sont les plus consommateurs en fonction de l'application.
