
TUTORIAL 8

1 Minimum of a List

You have a set of N numbers (N can be written on n bits) x_0, \dots, x_{N-1} than can be encoded on b bits and an access to a gate $U_x |i\rangle |y\rangle \rightarrow |i\rangle |y \oplus x_i\rangle$. We denote $[N] = \{0, \dots, N-1\}$.

In the following, we are going to use the "unknown target" version of Grover algorithm: UNK-GROVER. This is a version of Grover that finds a marked element in a list of N elements, and makes $O(\sqrt{N}/r)$ queries to the elements of the list where r is the (unknown) number of marked elements. UNK-GROVER succeeds with probability $\geq 2/3$ (that we can amplify).

1. Let $i \in [N]$. Explain how to adapt UNK-GROVER to find $j \in [N]$ such that $x_j < x_i$ if it exists.
How many queries to U_x does your algorithm makes?
2. We are going to study the following algorithm:

Algorithm 1 Find-Min

```

 $i \leftarrow U([N]).$ 
while 1 do
    Find  $j$  such that  $x_j < x_i$  with UNK-GROVER.
    If it is impossible, return  $i$ .
    Else,  $i \leftarrow j$ .
end while

```

- (a) How many calls to U_x makes algorithm 1 in the worst case?
- (b) Show that if x_j is the element of rank r , the probability that j is picked from the algorithm at some point is $1/r$. *Hint: induction on N* .
- (c) Compute an upper bound on the expected number of queries to U_x made by algorithm 1.
- (d) Conclude by proposing a quantum algorithm doing $O(\sqrt{N})$ calls to U_x that find a minimum in the x_i with probability $\geq 2/3$. *Hint: Markov*.

2 QMA, quantum generalization of NP

We consider the following complexity class: we say that a promise problem $L = (L_{\text{YES}}, L_{\text{NO}})$ is in the class **QMA** if there exist a polynomial-time classical algorithm \mathcal{C} such that $\mathcal{C}(x)$ is a quantum circuit realizing U_x , such that it satisfies the two following properties:

- **Completeness:** $x \in L_{\text{YES}} \Rightarrow \exists |\psi\rangle$ such that measuring the first qubit of $U_x |\psi\rangle \otimes |0\rangle$ gives 1 with probability $\geq \frac{2}{3}$
- **Soundness:** $x \in L_{\text{NO}} \Rightarrow \forall |\psi\rangle$, measuring the first qubit of $U_x |\psi\rangle \otimes |0\rangle$ gives 1 with probability $\leq \frac{1}{3}$

1. Show that **NP** \subseteq **QMA**.
2. Show that **BQP** \subseteq **QMA**.

3. Call $\mathbf{QMA}[c(n), s(n)]$ the variant of \mathbf{QMA} where the completeness error $\frac{2}{3}$ is replaced by $c(n)$ and the soundness error $\frac{1}{3}$ is replaced by $s(n)$. Can you prove that $\mathbf{QMA} = \mathbf{QMA}[c(n), s(n)]$ with $c(n) - s(n) \geq \frac{1}{p(n)}$ for a positive polynomial p ? We will nonetheless assume this result for this exercise.
4. Recall that the k -LOCAL HAMILTONIAN problem takes as input the description of $H = \sum_{j=1}^r H_j[S_j]$ acting on $(\mathbb{C}^2)^{\otimes n}$, with H_j k -local and $\text{sp}(H_j) \subseteq \{0, 1\}$ (so H_j is a projector), and parameters $0 < a < b$ with $b - a \geq \frac{1}{\text{poly}(n)}$. The goal is to output 1 if $\lambda_{\min}(H) \leq a$ and 0 if $\lambda_{\min}(H) \geq b$. We want to show that k -LOCAL HAMILTONIAN is in \mathbf{QMA} . We consider the following quantum algorithm:
 - Sample j uniformly in $\{1, \dots, r\}$
 - We can decompose $H_j = \sum_{i=1}^{n_j} |b_i^j\rangle\langle b_i^j|$, with $(|b_i^j\rangle)_{i \in [n]}$ basis of $(\mathbb{C}^2)^{\otimes n}$. Apply the change of basis V_j such that $V_j^\dagger = (|b_i^j\rangle)_{i \in [n]}$, measure in the standard basis. If the output $i \notin [n_j]$, then output 1; else output 0.
 - (a) Justify why we can construct such a quantum algorithm with a polynomial-size quantum circuit using ancillas and measuring only its first output.
 - (b) On input $|\eta\rangle$, first compute the probability that given j , you get 1. Then prove that the global probability of getting 1 is $1 - \frac{\langle \eta | H | \eta \rangle}{r}$.
 - (c) Find a lower bound on the probability of outputting 1 in the completeness part of \mathbf{QMA} for the k -LOCAL HAMILTONIAN using the certificate $|\eta\rangle$, where $|\eta\rangle$ is an eigenvector of H for eigenvalue $\lambda_{\min}(H)$, under the hypothesis that $\lambda_{\min}(H) \leq a$.
 - (d) Find an upper bound on the probability of outputting 1 in the soundness part of \mathbf{QMA} for the k -LOCAL HAMILTONIAN under the hypothesis that $\lambda_{\min}(H) \geq b$.
 - (e) Conclude.

Remark. The k -LOCAL HAMILTONIAN is in fact \mathbf{QMA} -complete for $k \geq 2$. □

3 Matrix Exponentials

1. Compute $\exp(iX)$, $\exp(iZ)$, $\exp(iX) \cdot \exp(iZ)$, $\exp(i(X + Z))$.
2. **Tail-cut of the matrix exponential.** Assume that A is a matrix of norm ≤ 1 . Let $0 < \varepsilon < 0.99$ and $t > 0$. Show that there exists a constant $c > 0$ independant of A, ε and t such that:

$$\left\| \sum_{k=0}^{c \cdot (t + \log(1/\varepsilon))} \frac{(itA)^k}{k!} - \exp(itA) \right\| < \varepsilon .$$

You can use freely that $k! \leq \left(\frac{k}{e}\right)^k$.

3. What tail-cut bound do you have to take if $\|A\| \leq 1$ is not supposed anymore?
