

Executable Knowledge

for rule-based modelling
of cellular signalling networks

Context

Cellular signalling

- Decentralized coordination of tissue formation and maintenance
 - *extra*-cellular ligands trigger *intra*-cellular **signalling pathways** to control cell growth, death, division, ...
- Perturbed in disease states, *e.g.* cancer, diabetes, ...
 - **kinetic** perturbations: over-expression, knock-outs, ...
 - **causal** perturbations: mutations, truncations, ...

Why model signalling?

- Signalling networks, *and their literature*, are mind-bogglingly complicated
 - 1000s of proteins and 10s (or even 100s) of thousands of PPIs [protein-protein interactions]
 - empirical knowledge is fragmented and scattered across a vast literature
 - impossible to ‘work out’ in your head

Traditional modelling

- Modelling as a primarily ‘mental’ activity
 - identify the **key variables** *and* their **inter-dependencies** under *standard* perturbations
 - amounts to making **model-level assumptions** *during* model construction and ‘debugging’
 - model as ‘**synthesis** of understanding’

Traditional modelling

- To put it differently:
 - the **modelling** is done ‘in your head’
 - the **model** is an artifact that emerges fully-formed and is just ‘written down’
 - the model is then debugged if it fails to meet your mental ‘specification’

Modelling signalling

- Signalling needs models as ‘tools for discovery’
 - a formal reification of the **modelling process** [rather than just the resulting artefact] as an ‘audit trail’
 - *precisely in order to* achieve an understanding
 - reverse-engineer a **specification** by combining **empirical knowledge** with (biological) **inference**

Modelling signalling

- Models must therefore
 - be *easily* **extensible** and **modifiable** [since empirical knowledge is always changing]
 - be *arbitrarily* **perturbable** [since we wish to discover, not hard-wire, their effects]
 - incorporate **empirical** and **inferred** knowledge [at various levels of detail]

Rule-based modelling

- **Formal** representation for the (10s? of 1000s of) protein-protein interactions (**PPIs**) in signalling
 - **graph rewriting** formalism
 - **scalable** stochastic simulation
 - pathways as **causal traces**
- Handles **kinetic**, but not **causal**, perturbations

Serendipity

The cognitive barrier

- Have to **read many** papers to find various **fragments** of knowledge about a **single PPI**
- many different ‘puzzle pieces’, at **varying** levels of detail, that must [somehow] be **assembled** into rules
- the **effects** of causal perturbations must be hard-wired by **enumerating** all cases [rather than emerging]
- **not scalable** for a human curator [believe me, I’ve done it]

Big Mechanism

- Seeks **causal explanations** of complex system behaviour [not ‘just’ **correlations**]
- **Machine reading** of papers, automatic **assembly** into models that yield causal **explanations** ...
- The chosen **use case**: signalling pathways in cancer!

Breaching the cognitive barrier

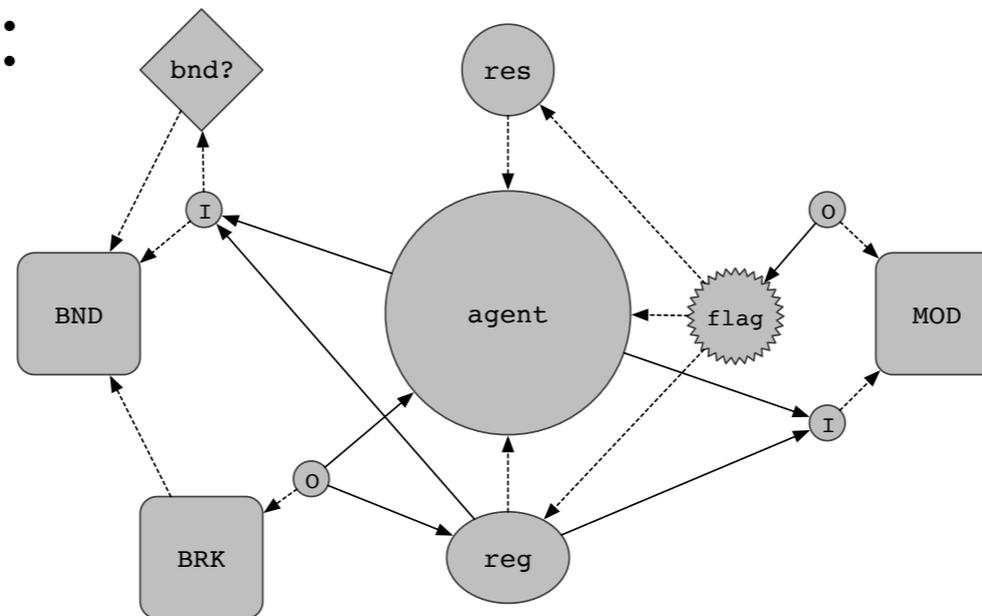

Assembly

- Big Mechanism aims to make **reading** **scalable** and RBM **provides** causal **explanations** — **once** your PPIs have been formalized as rules
- The hard problem is **assembly**
 - combining fragments of knowledge into rules ...
 - ... in such a way that (apparently) **conflicting** information can be accommodated ...
 - ... and the effects of causal perturbations **emerge**

KAMI

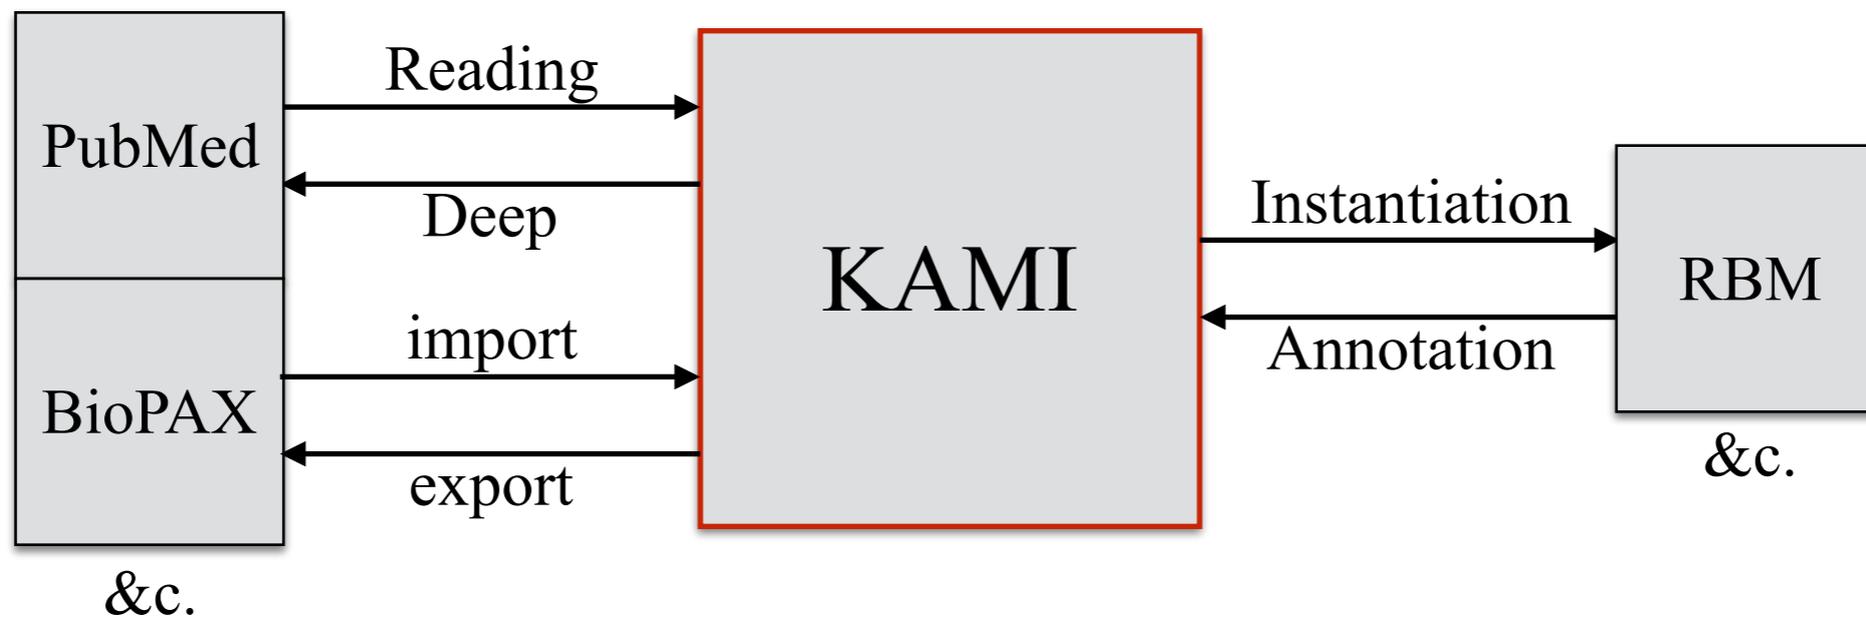

knowledge aggregator & model instantiator

- Uses a **graph**-based representation of PPIs
- a graph with two directed edge structures, respecting a **meta-model**:

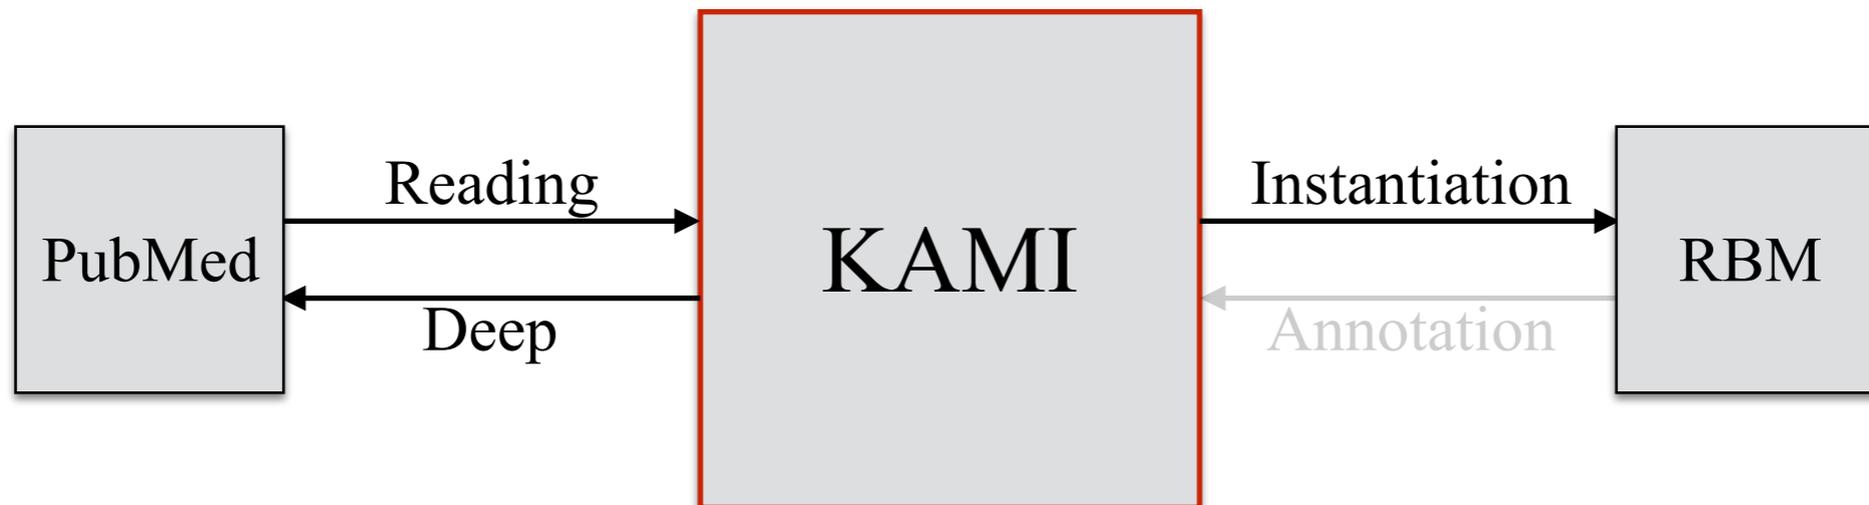

- uses graph rewriting to **update** and **aggregate** PPIs

in BigM

(KAMI)

read

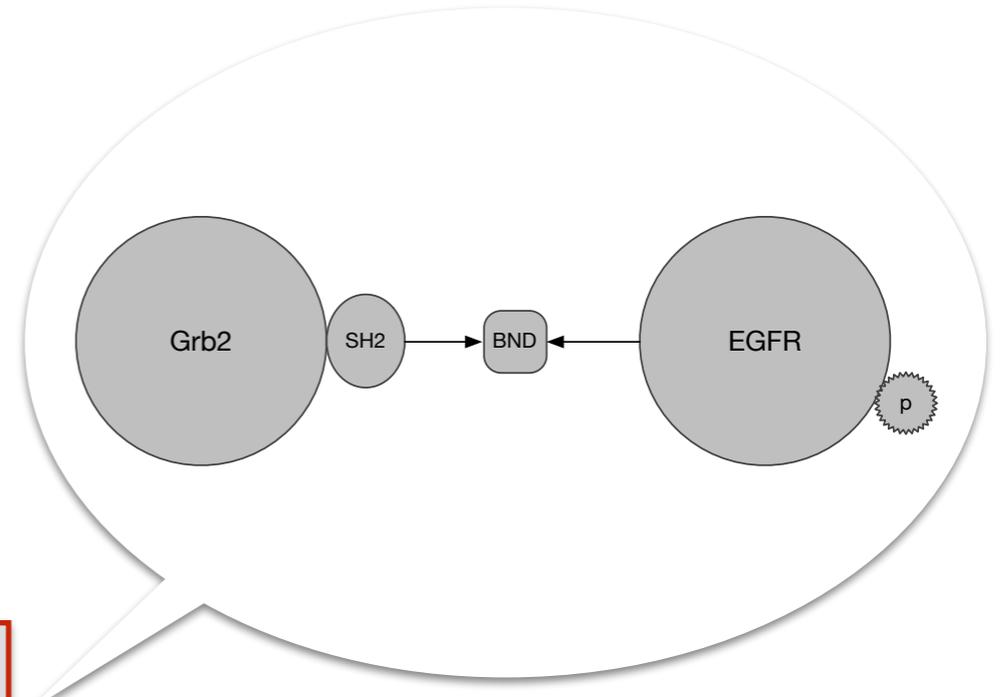

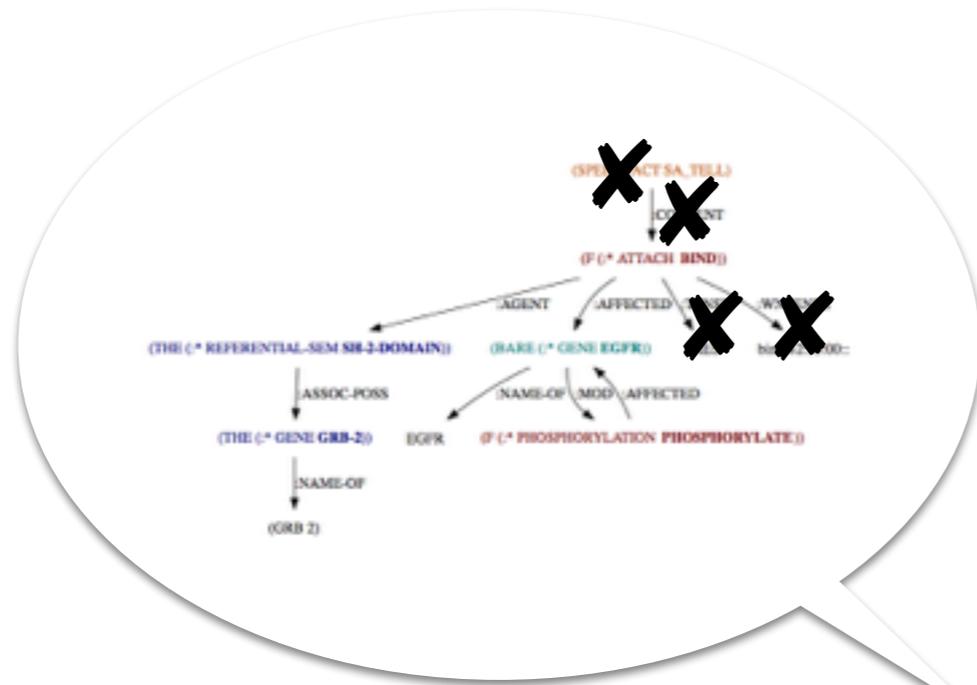

“Grb2’s SH2-domain binds phosphorylated EGFR”

thanks to Lucian
Galescu *et alia!*

KAMI

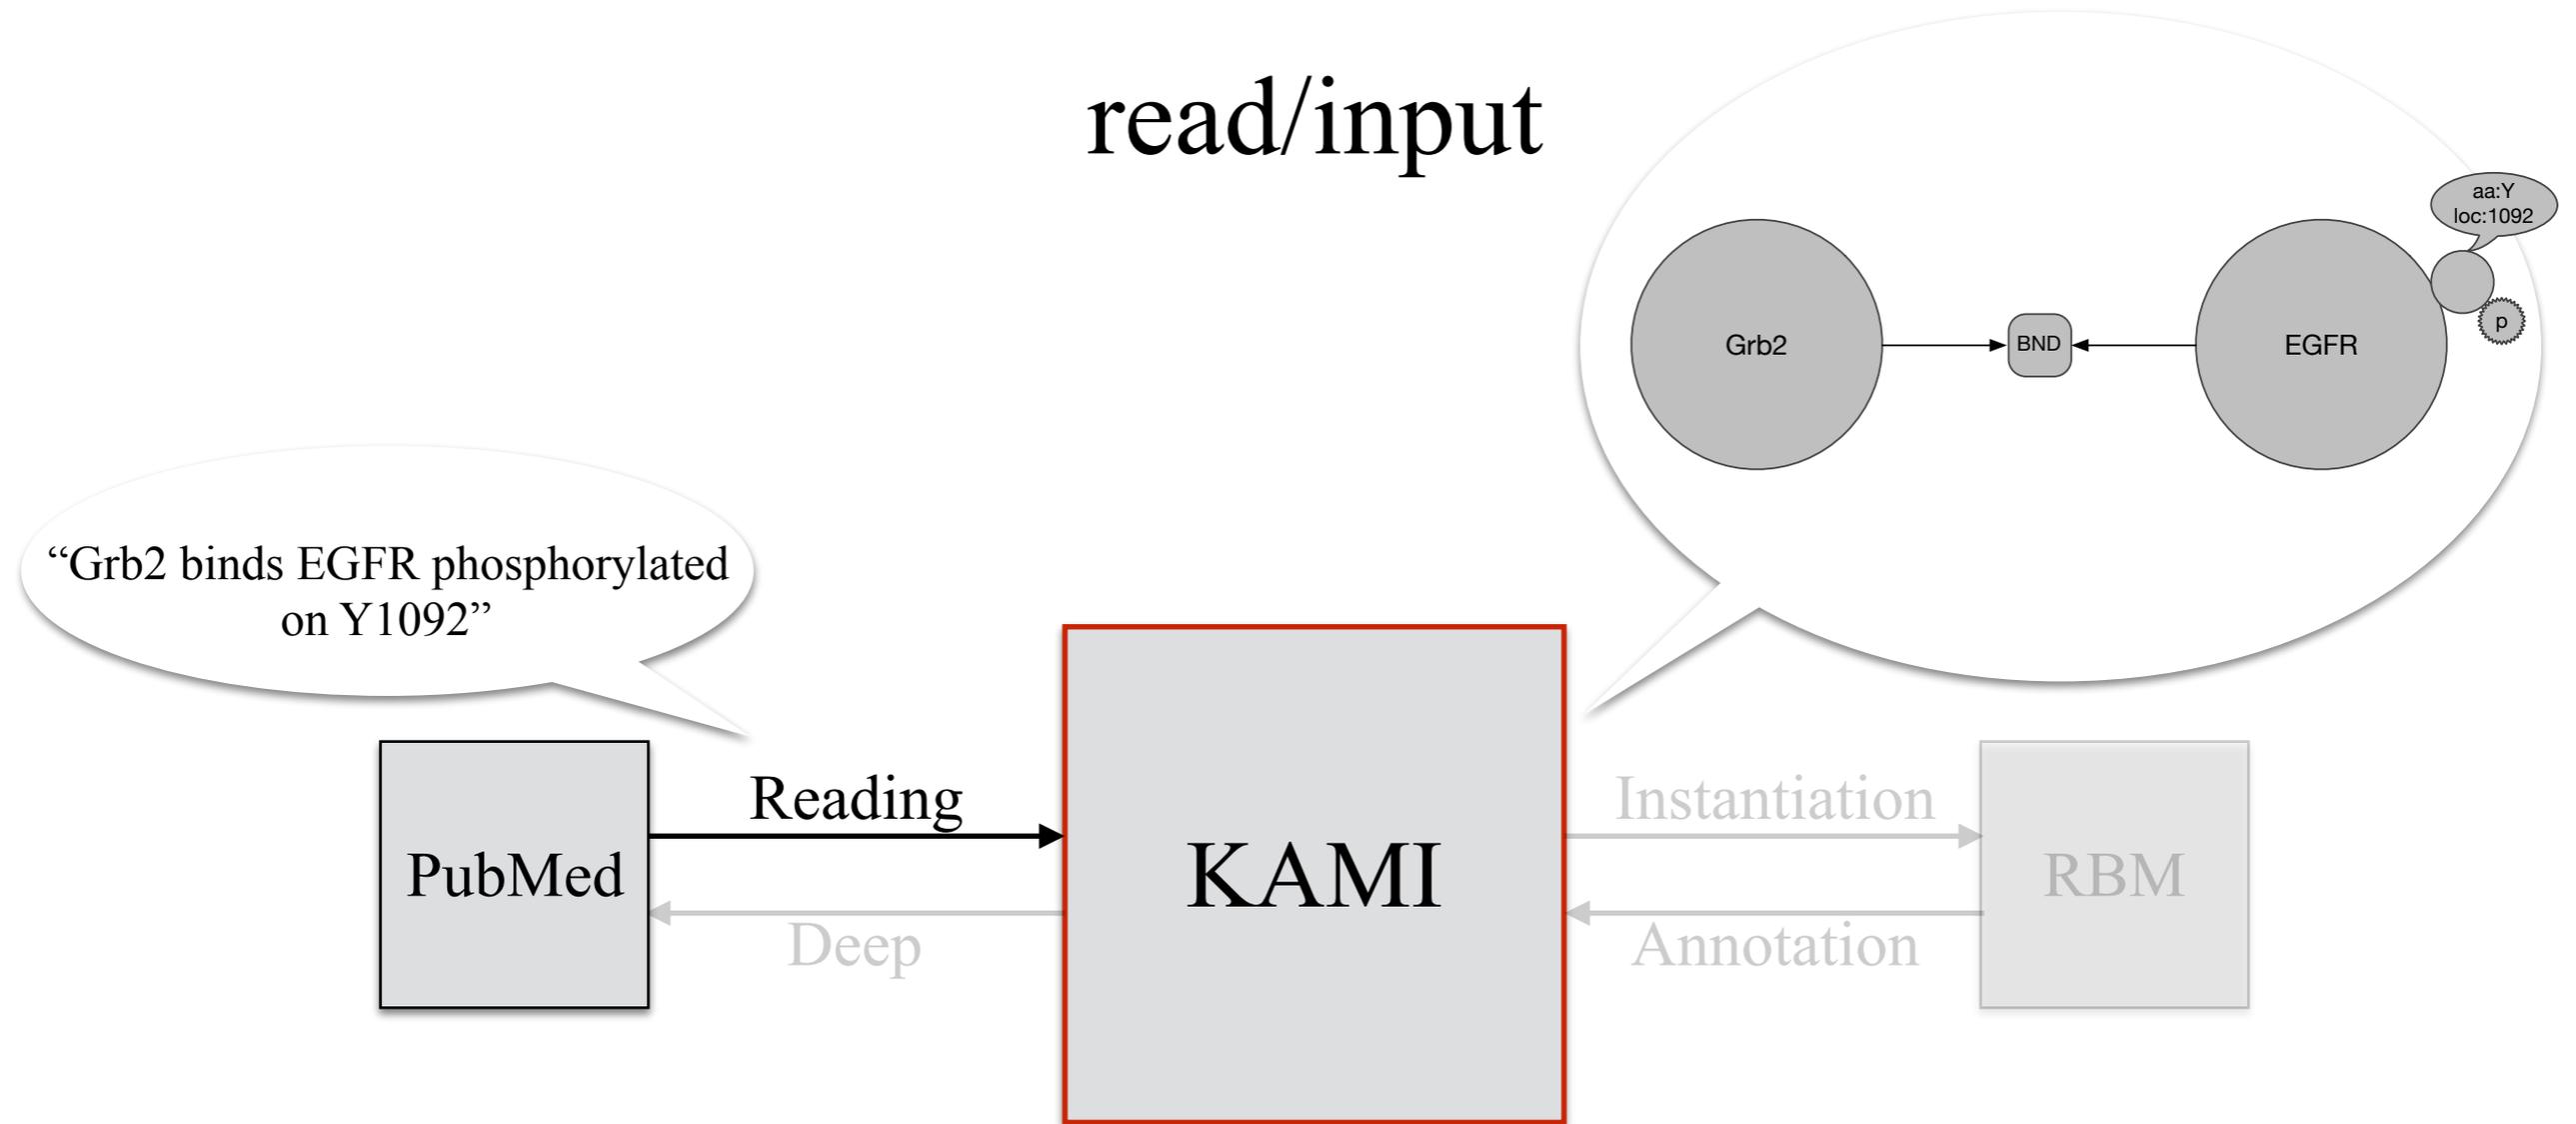

input

thanks to Ben Gyori
& John Bachman!

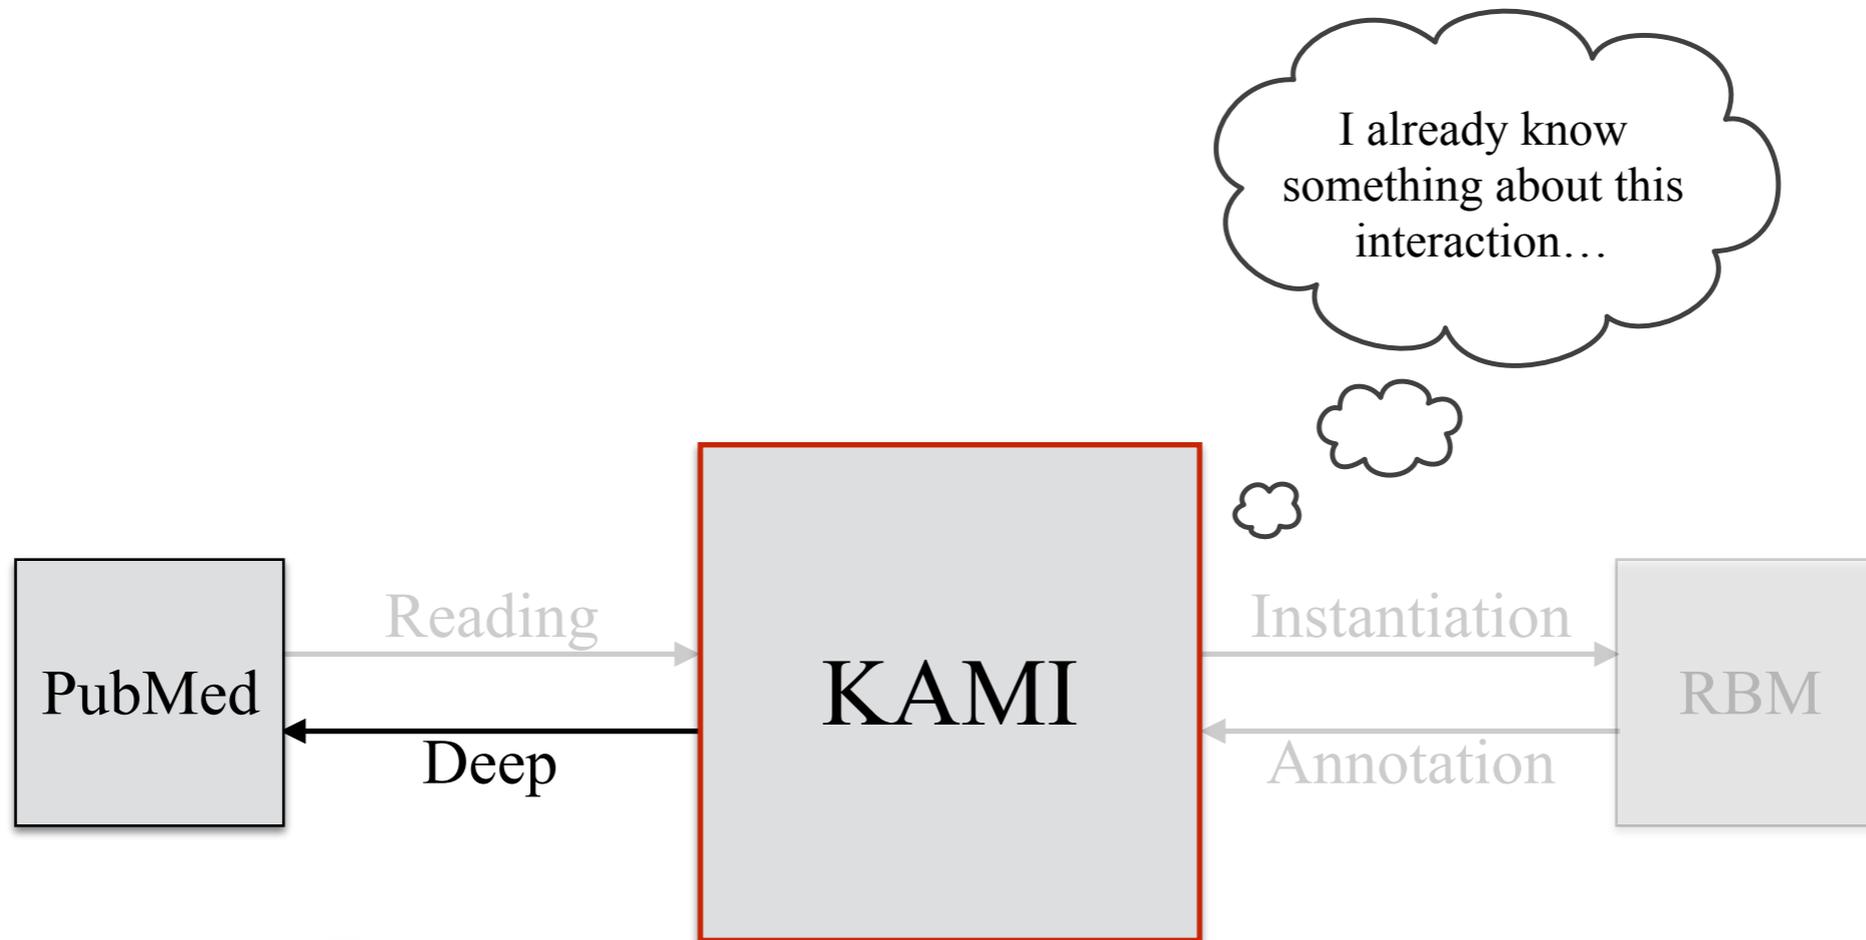

KAMI

read/input

KAMI

deep reading

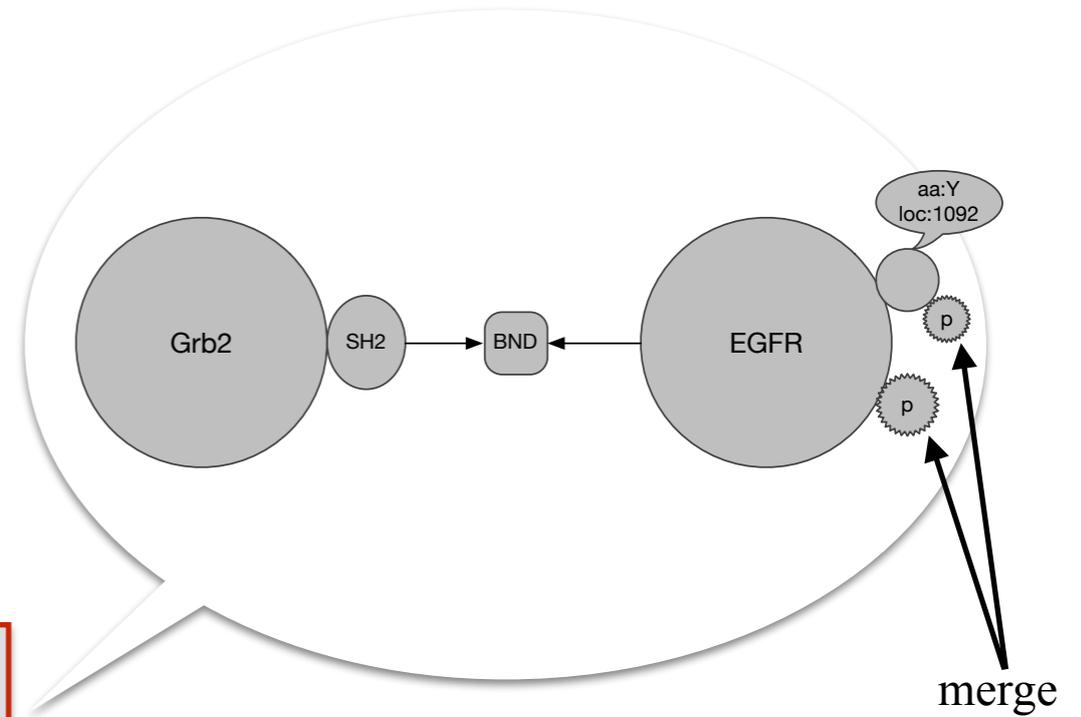

“Grb2’s SH2-domain binds [phosphorylated] EGFR phosphorylated on Y1092”

**this is not yet fully automated:
requires a semantic layer**

KAMI

update

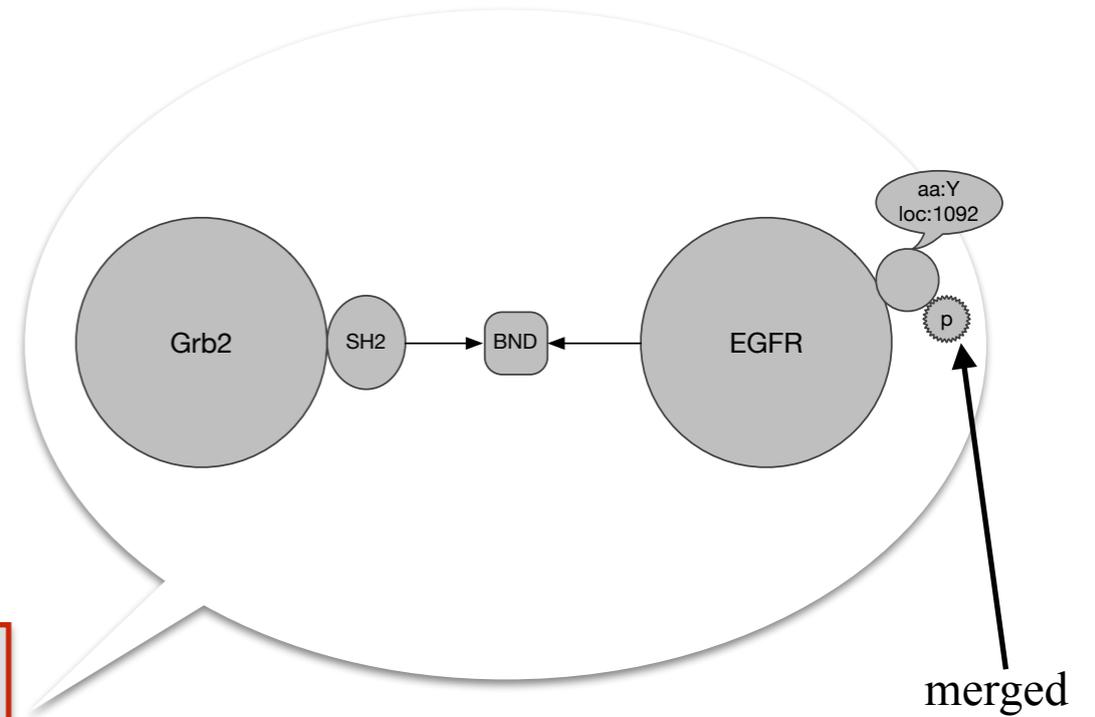

“Grb2’s SH2-domain binds [phosphorylated] EGFR phosphorylated on Y1092”

this is a step of graph rewriting

KAMI

update

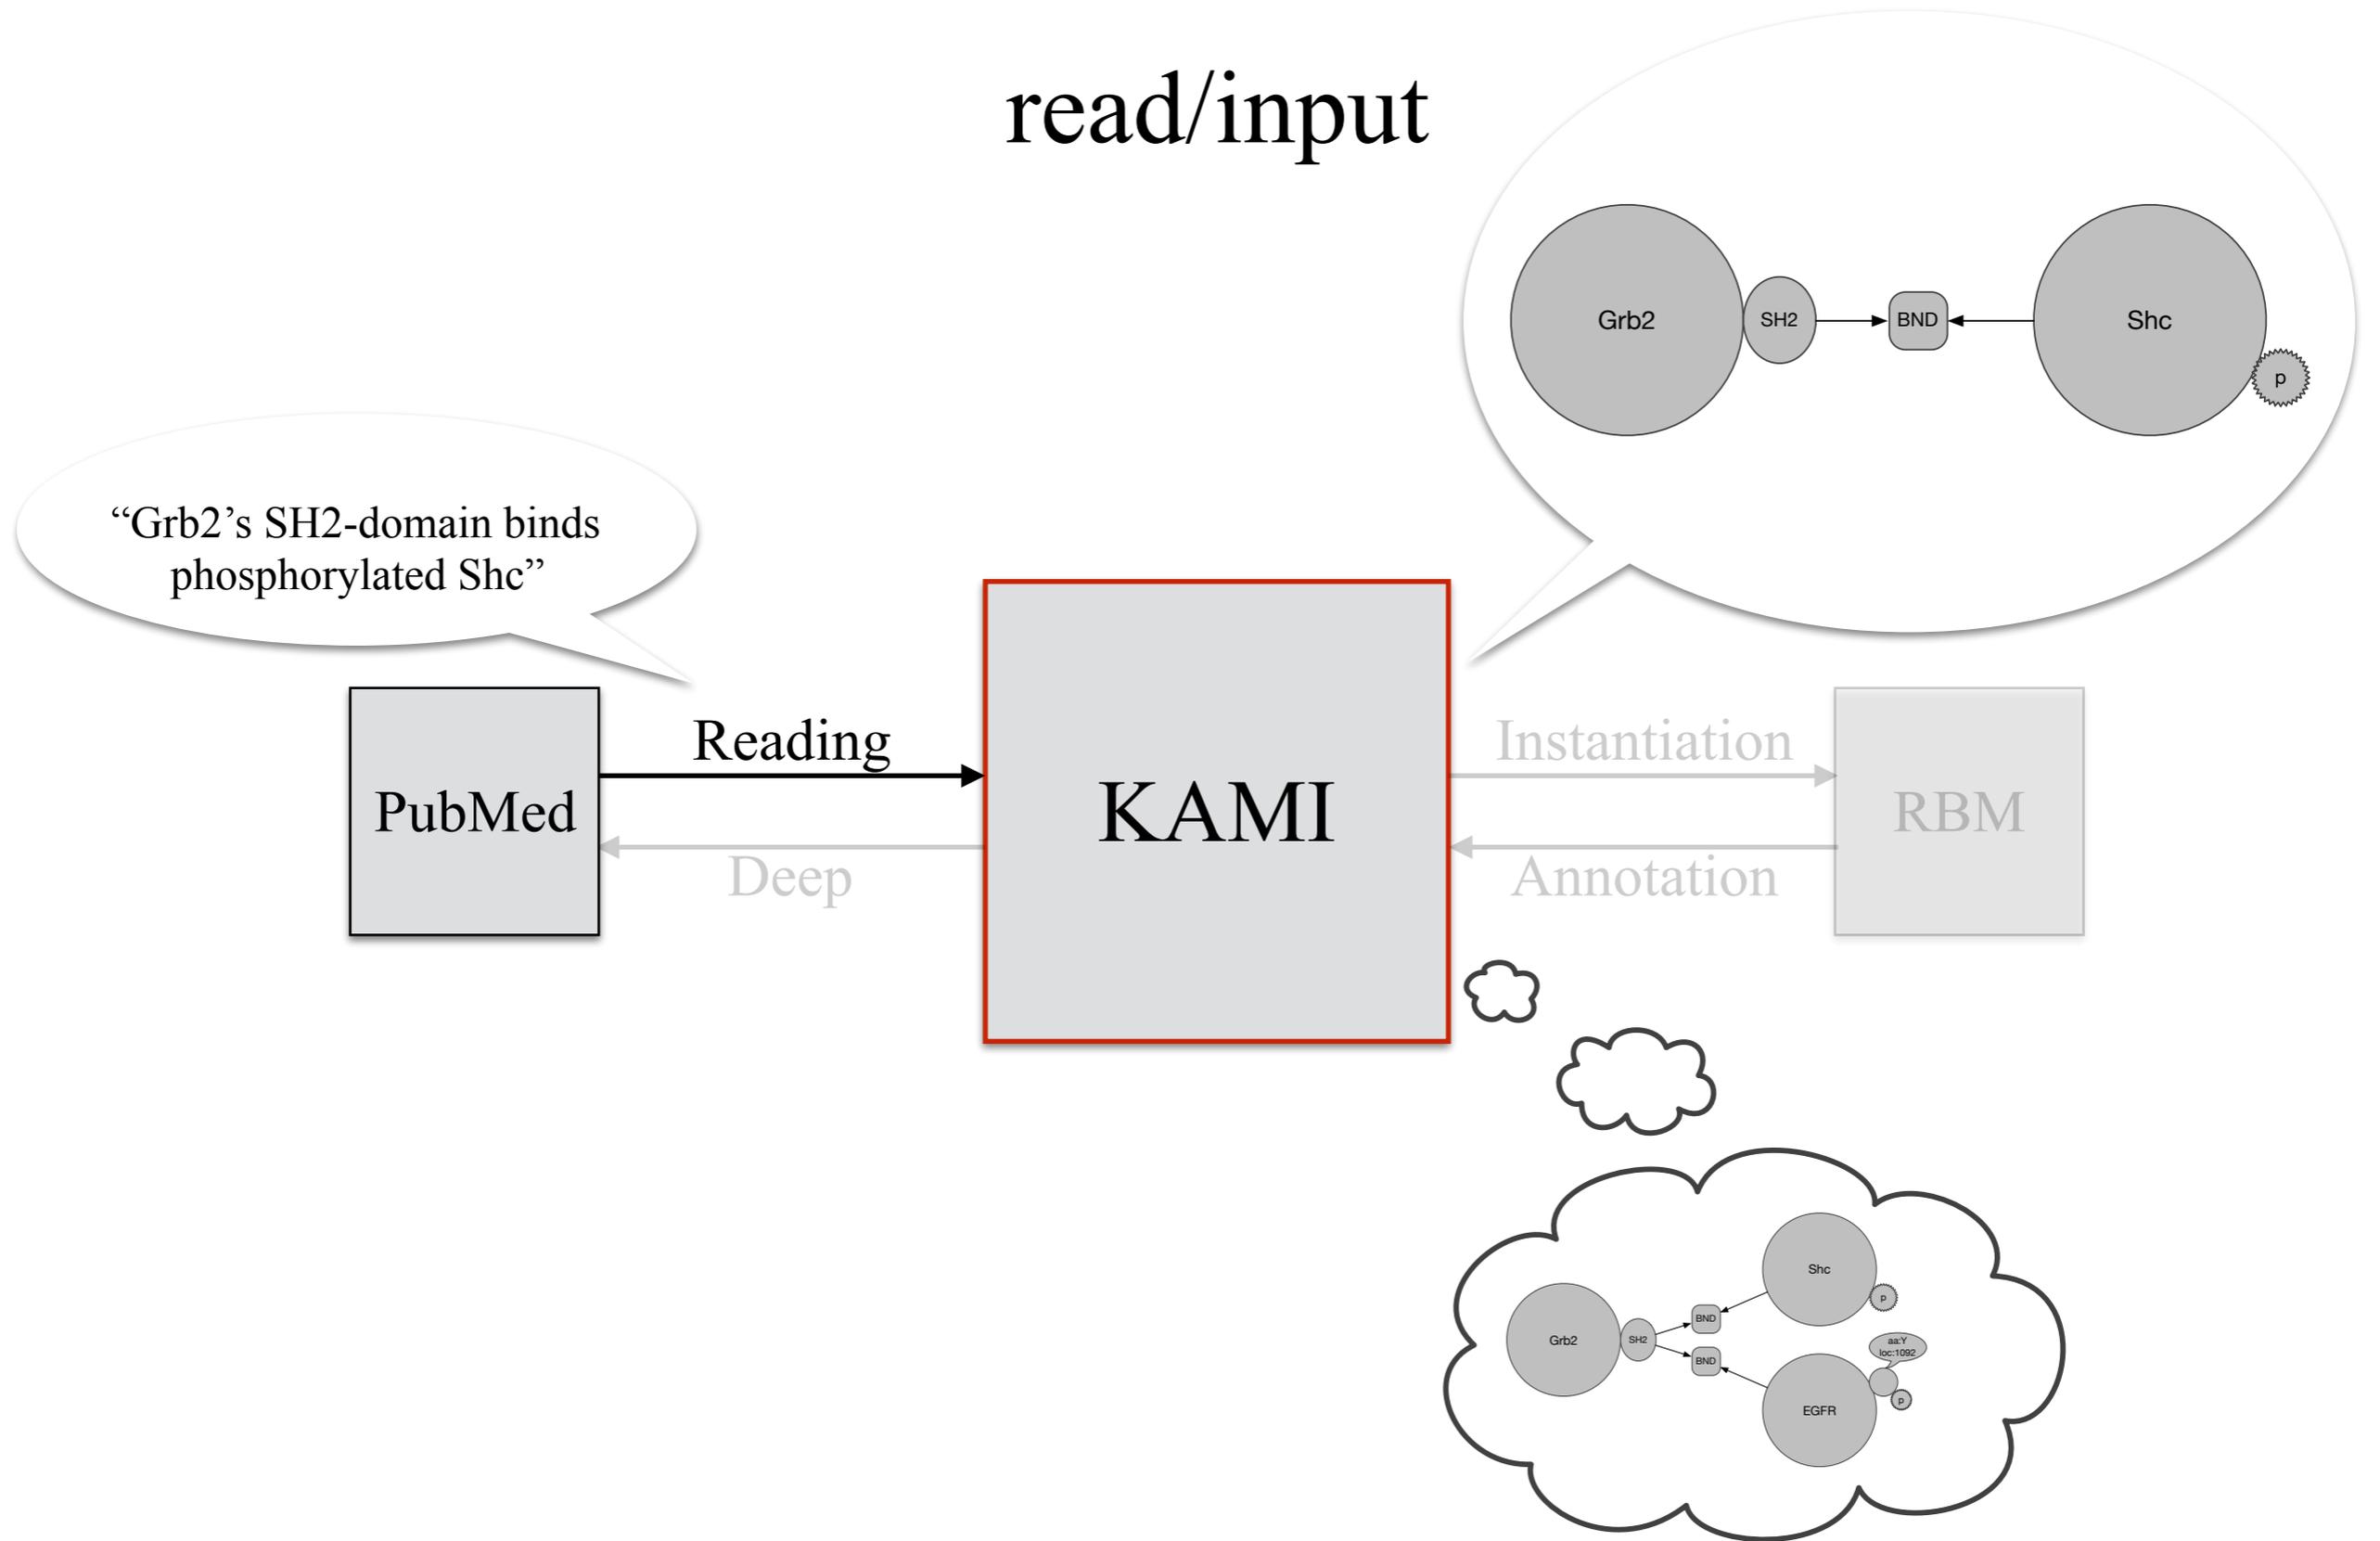

“Grb2’s SH2-domain binds [phosphorylated] EGFR phosphorylated on Y1092”

this is another step of graph rewriting

Wrapping up

Summary

- A purely formal graph rewriting foundation
 - represents **knowledge** and [revokable] **hypotheses** using formal operations of (**update** and) **aggregation**
- Model **instantiation** into RBM
 - **automatically** maintains desired [conflict] **invariants** and handles the effects of **mutations** because all enumeration is done by the **machine**

Automation?

- Other than an **expert** user, where could the steps of rewriting come from?
- **semantics**: typically steric or functional properties of certain regions, e.g. SH2 or kinase domains
 - also allows for semantic checking and inference
- more general **inference** ...

Work in progress

- Open re-implementation as a Python library
 - **standard** meta-models and meta-model transformations
 - can also be **user-defined**
- Based on a graph rewriting Python library
 - itself built on top of NetworkX
 - **multi-level** rewriting with upward **propagation**
