Introduction to core convection

Thierry Alboussière

Laboratoire de Géologie de Lyon

juillet 2021 École d'été de Géophysique Interne, Les Houches

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Overview

- 1. Evidence for convection in the core
- 2. Driving forces
- 3. Physical properties of the core
- 4. Governing equations for convection
- 5. So many waves... geostrophy and turbulence

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

6. Convection in the inner core

1. Evidence for convection in the core

- 1906, Richard Oldham, existence of the core
- 1913, Beno Gutenberg, CMB within 1%
- 1919, Joseph Larmor, "dynamo effect" for the Sun (and Earth)
- 1926, Harold Jeffreys, liquid core
- 1946, Walter Elsasser, Earth's dynamo

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Geomagnetism

- Back in 1633, Henry Gellibrand discovers magnetic variation
- ▶ 1906, Bernard Brunhes discovers magnetic reversals
- 1949, Louis Néel discovers (anti)ferromagnetism
- 1600 present days, measurements of declination (naval traffic, magnetic observatories, satellite data)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Magnetic data

CHAOS-2s, Olsen et al., 179:3, JGI, 2009

Velocity at the top of the core

$$\frac{\partial B_r}{\partial t} = -\nabla_s \cdot (B_r u_s) \qquad \sim 20 \text{ km/year}$$

a) 1840 b) 1890 c) 1940 d) 1990 Amit and Olson, PEPI, 155, 2006

Seismic radial profiles

Figure 7.2. PREM model: Seismic velocities and density profile (after Dziewonski and Anderson 1981).

PREM radial model: isentropic outer core by construction

(日) (四) (日) (日) (日)

Seismic radial profiles: bottom dense layer

Other models, not bounded by the isentropic hypothesis

Kennett *et al.*, *GJI*, **122**, 1995, ak135 Song and Helmberger, *JGR*, **100**, 1995, PREM2

And at the top of the core?

No definite seismic observation, but a few reasons in favour of its existence

- light elements from the inner core crystallization might end up there
- light elements from exsolution might end up there
- diffusion of light elements from the mantle

and a few against its existence

- existence of 'fast' geomagnetic variations (jerks)
- upwellings/downwellings in core velocity models

2. Driving forces

- Thermal cooling from the top
- Composition buoyancy at the ICB
- Precessional forcing
- Compositional buoyancy from exsolution

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Radiogenic heating?

Thermal convection

Thermal convection

 of which 5 to 15 TW extracted from the core: start a debate here...

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶

Compressible convection

- Entropy mixing
- In a hydrostatic pressure gradient
- Produces an adiabatic (isentropic) temperature gradient

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- Because iron is a good thermal conductor
- Generates a significant conduction flux

Compressible convection

- Only a heat flux exceeding the flux conducted along the adiabat can generate convection (Schwarzschild 1906, Adams-Williamson 1923, Jeffreys 1930)
- A smaller flux is conducted along a stable temperature gradient: no motion

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

That condition may depend on depth and epoch

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ ─臣 ─の�?

Compositional convection

The density jump across the ICB (590 kg m⁻³ in PREM, 850 kg m⁻³ for normal modes and ICB reflexion) is due to

- ▶ phase change (latent heat) 200 to 240 kg m⁻³
- fractionation of light elements (H,Si,0,S,C,...)

Generally considered as the strongest source of convection...

liquid core: 6 to 10% less dense than liquid iron inner core: 2 to 3% less dense than solid

Compositional convection in experiments

Crystallization of an ammonium chloride solution NH_4CI

Huguet et al., 204, GJI, 2016

Compositional convection in experiments

Huguet et al., 204, GJI, 2016

Phase diagram NH₄Cl in water

・ロト・西・・田・・田・・日・

Specificity of compositional convection

- Its strength is directly linked to that of thermal convection: because thermal cooling is directly responsible for inner core crystallization
- However, molecular diffusivity of species is much smaller than thermal diffusivity, by three to four orders of magnitude $Le = \kappa/D \sim 10^4$

Origin of double-diffusive effects

Double diffusion

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

Precession

Equatorial buldge leads to precession: 25772 years, 23.5 $^\circ$

Precession of Moon's orbit generates nutations: 18.6 years, 9.2 "

3. Physical properties of the liquid core

density

- heat capacity
- thermal expansion
- viscosity
- thermal conductivity
- electrical conductivity

and what is the temperature of the core?

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Density

Figure 7.2. PREM model: Seismic velocities and density profile (after Dziewonski and Anderson 1981).

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

Heat capacity

The law of Dulong and Petit is enough: "six calories per gram atom", *i.e.* $C_p = 3R$ with R = 8.314 J K⁻¹mol⁻¹ the ideal gas constant

Moreover, c_p and c_v are very similar in condensed matter.

Coefficient of thermal expansion

 $) \land (\land)$

Viscosity

General agreement for small values $\eta\simeq 10^{-3}~{\rm Pa}~{\rm s}$ Except Smylie in a few papers on Slichter modes...

Its value was considered to be around 30 W m⁻¹K⁻¹ from the 70's (Matassov PhD thesis, shock experiments, 1977; Stacey and Davis, *Physics of the Earth*, CUP, 2008), but re-evaluated in the last 10 years.
Thermal conductivity

A crucial, determining, parameter for convection, because thermal conduction along the adiabatic gradient is a significant part of the total radial heat flux.

(日) (四) (日) (日) (日)

Electrical conductivity

- Important for dynamo action!
- Wiedemann–Franz law: $\frac{k}{\sigma} = LT$, where $L = \frac{\pi^2}{3} \left(\frac{k_B}{e}\right)^2 \simeq 2.44 \ 10^{-8} \ W \ \Omega \ K^{-2}$ is the Lorenz number

was hence also revised upward recently

Electrical conductivity

Gomi et al., PEPI, 224, 2013

$$\sigma \simeq 10^6 \ \Omega^{-1} \mathrm{m}^{-1}$$

4. Governing equations for convection

Convection

- Navier-Stokes with Coriolis and Lorentz forces
- Induction equation
- Adiabatic gradient and superadiabatic forcing

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Convection equations

Mass conservation

$$rac{\partial
ho}{\partial t} +
abla \cdot (
ho { extbf{v}}) = 0$$

Momentum conservation (Navier-Stokes)

$$\rho \frac{\mathrm{D} \mathbf{v}}{\mathrm{D} t} = -\nabla P + \rho \mathbf{g} + \nabla \cdot \tau \qquad \qquad \tau : \text{ deviatoric} \\ \text{stress tensor}$$

Energy conservation (or entropy equation)

$$\rho T \frac{\mathrm{D}s}{\mathrm{D}t} = \dot{\varepsilon} : \tau + \nabla \cdot (k \nabla T)$$

and an equation of state EoS: $T = T(\rho, s)$, $P = P(\rho, s)$

$$egin{split} \dot{arepsilon}_{ij} &= 1/2 \left(\partial_i \mathsf{v}_j + \partial_j \mathsf{v}_i
ight) \ au_{ij} &= 2\eta \left(\dot{arepsilon}_{ij} - rac{1}{3} (
abla \cdot \mathsf{v}) \delta_{ij}
ight) \end{split}$$

▲□▶ ▲冊▶ ▲臣▶ ▲臣▶ 三臣 - 釣�?

The 'adiabatic' gradient

In a well-mixed fluid, entropy is uniform. In addition, the fluid is often close to hydrostatic equilibrium.

$$\begin{aligned} \mathbf{d}s &= \frac{\partial s}{\partial P} \Big|_{T} \mathbf{d}P + \frac{\partial s}{\partial T} \Big|_{P} \mathbf{d}T = \mathbf{0} \\ &\frac{\partial s}{\partial P} \Big|_{T} = -\frac{\alpha}{\rho} \qquad \mathbf{d}G = -s\mathbf{d}T + \frac{1}{\rho}\mathbf{d}P \\ &\frac{\partial s}{\partial T} \Big|_{P} = \frac{c_{P}}{T} \qquad \mathbf{d}H = T\mathbf{d}s + \frac{1}{\rho}\mathbf{d}P = c_{\rho}\mathbf{d}T + \frac{\partial H}{\partial P} \Big|_{T} \mathbf{d}P \\ &\text{Hence} \quad \frac{\partial T}{\partial P} \Big|_{s} = \frac{\alpha T}{\rho c_{\rho}} \longrightarrow \qquad \boxed{\frac{\mathbf{d}T}{\mathbf{d}z} = -\frac{\alpha gT}{c_{\rho}}} \end{aligned}$$

Earth's convection

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

Adiabatic (isentropic) temperature profile

 T_a (dashed line) is the 'adiabatic' temperature profile. We also define ρ_a , P_a , c_{pa} , α_a ...

Stable temperature profile

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 _ のへで

Unstable temperature profile

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 _ のへで

Anelastic (liquid) approximation

continuity
$$\frac{\partial \rho}{\partial t} = -\nabla \cdot (\rho \mathbf{v})$$
 $\nabla \cdot (\rho_a \mathbf{v}) = \mathbf{0}$
Navier-Stokes $\rho \frac{\mathrm{D} \mathbf{v}}{\mathrm{D} t} = -\nabla P + \rho \mathbf{g} + \nabla \cdot \tau$
 $\rho_a \frac{\mathrm{D} \mathbf{v}}{\mathrm{D} t} = -\rho_a \nabla \left(\frac{P}{\rho_a}\right) + \rho_a \alpha_a T' g \hat{\mathbf{e}}_z + \nabla \cdot \tau$

entropy $\rho T \frac{\mathrm{D}s}{\mathrm{D}t} = \dot{\epsilon} : \tau - \nabla \cdot \phi$

$$\rho_{a} \frac{\mathrm{D}(c_{pa}T')}{\mathrm{D}t} = -\rho_{a}\alpha_{a}g T' v_{z} + \dot{\epsilon} \colon \tau + \nabla \cdot (k\nabla(T' + T_{a}))$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへ⊙

Heat flux

The heat flux is the sum of the conduction flux along the adiabat and the extra flux driven by the superadiabatic temperature difference ΔT_{sa}

$$\Phi = k \frac{\Delta T_a}{H} + Nu \ k \frac{\Delta T_{sa}}{H}$$

where Nu is the resulting dimensionless heat flux, that must be a function of the dimensionless parameters defining the problem

$$Ra = \frac{\alpha g \Delta T_{sa} H^3}{\nu \kappa}$$
$$Pr = \frac{\nu}{\kappa}$$
$$\mathcal{D} = \frac{\alpha g H}{c_p}$$

Rayleigh, Prandtl and Dissipation number

Heat flux

Niemela *et al.*, Nature, vol. 404, 2000

Lülff *et al.*, New J. of Phys., vol. 13, 2011

<ロ> (日) (日) (日) (日) (日)

Heat flux

Assuming

- a heat flux conducted along the adiabat of 3 to 10 TW
- a superadiabatic flux of 1 to 10 TW
- \blacktriangleright vertical velocities of 10^{-4} m s⁻¹

Hence the convective heat flux $\rho c_p v \Delta T_{sa}$ can transfer easily 10 TW with

$$\Delta T_{sa} \sim 10^{-4}~{
m K}$$

Superpowers of core convection!

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Then the Rayleigh number is

$$Ra = rac{lpha \, \mathrm{g} \, \Delta T_{sa} H^3}{
u \kappa} \sim 10^{23}$$

Navier-Stokes has an extra force term in a rotating frame of reference

$$\rho_{a} \frac{\mathrm{D}\mathbf{v}}{\mathrm{D}t} = -2\,\rho_{a}\,\Omega \times \mathbf{v} - \rho_{a}\nabla\left(\frac{P}{\rho_{a}}\right) + \rho_{a}\alpha_{a}\,T'g\hat{\mathbf{e}}_{z} + \nabla\cdot\tau$$

▲□▶ ▲圖▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへぐ

Electromagnetic coupling

$$\rho_{a}\frac{\mathrm{D}\mathbf{v}}{\mathrm{D}t} = -2\,\rho_{a}\,\Omega\times\mathbf{v} + \mathbf{j}\times\mathsf{B} - \rho_{a}\nabla\left(\frac{P}{\rho_{a}}\right) + \rho_{a}\alpha_{a}\,T'g\hat{\mathbf{e}}_{z} + \nabla\cdot\tau$$

where $\mathbf{j} = \nabla \times \mathbf{B} / \mu_0$ and the magnetic field obeys the induction equation

$$rac{\partial \mathsf{B}}{\partial t} =
abla imes (\mathsf{v} imes \mathsf{B}) +
abla imes \left(rac{1}{\mu_0 \sigma}
abla imes \mathsf{B}
ight)$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

and $\nabla \cdot \mathsf{B} = \mathsf{0}$

5. So many waves...geostrophy and turbulence

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

- inertial waves
- geostrophy
- Alfvén waves
- torsional waves
- big gyre, LOD variations
- turbulence

Inertial waves (general method)

Ignore viscosity, non-linear inertia, Lorentz forces, buoyancy, density variations...

$$\frac{\partial \mathbf{v}}{\partial t} = -2\,\mathbf{\Omega} \times \mathbf{v} - \nabla P$$

We can take the curl to remove pressure

$$\frac{\partial (\nabla \times \mathbf{v})}{\partial t} = -2 \, \nabla \times (\Omega \times \mathbf{v})$$

Expand the possible velocity fields as planar waves

$$\mathbf{v}(\mathbf{x},t) = \hat{\mathbf{v}}(\mathbf{k},t)e^{i(\mathbf{k}\cdot\mathbf{x}-\omega t)}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Inertial waves (general method)

After substitution in Navier-Stokes

 $\omega \mathbf{k} \times \hat{\mathbf{v}} = 2 i (\mathbf{k} \cdot \Omega) \hat{\mathbf{v}}$

Taking another $k \times$ product leads to

$$\omega \mathbf{k} \times \mathbf{k} \times \hat{\mathbf{v}} = -4(\mathbf{k} \cdot \Omega)^2 \hat{\mathbf{v}}$$

We do not forget the continuity equation, $\nabla\cdot v=0$

$$\mathbf{k}\cdot\hat{\mathbf{v}}=\mathbf{0}$$

Then the wave equation becomes

$$-\omega^2 k^2 \hat{\mathbf{v}} = -4(\mathbf{k} \cdot \mathbf{\Omega})^2 \hat{\mathbf{v}}$$

Dispersion relation

$$\omega^2 k^2 = 4(\mathbf{k} \cdot \Omega)^2$$
 hence

$$\omega = \pm 2 \frac{\mathbf{k} \cdot \Omega}{\mathbf{k}}$$

Phase and group velocities

Phase velocity
$$\omega/k$$
, or in 3D $\omega/k \hat{\mathbf{e}}_k$

$$\left(2\Omega\frac{k_xk_z}{k^3}, 2\Omega\frac{k_yk_z}{k^3}, 2\Omega\frac{k_z^2}{k^3}\right)$$

Group velocity $\partial \omega / \partial k$, or in 3D $\partial \omega / \partial k_i$

$$\left(-2\Omega\frac{k_xk_z}{k^3},-2\Omega\frac{k_xk_z}{k^3},2\Omega\frac{k^2-k_z^2}{k^3}\right)$$

Properties

- phase and group velocities are orthogonal
- maximum phase velocity in the direction Ω
- minimum in perpendicular directions, but max group velocity along Ω

Geostrophy

When a flow is indepedent of z, it escapes inertial waves and there can be an equilibrium between Coriolis and pressure gradient. This is

geostrophic balance

- atmosphere
- oceans
- Jupiter, Saturn ?
- Earth's core ?

Vidal and Schaeffer, GJI, 202:3, 2015

・ロト・日本・日本・日本・日本・日本

Alfvén waves

In a uniform magnetic field B_0 along z, the linear coupled equations of Navier-Stokes and induction lead to

$$\frac{\partial^2 \mathbf{v}}{\partial t^2} = \frac{B_0^2}{\rho \mu_0} \frac{\partial^2 \mathbf{v}}{\partial z^2}$$

Alfvén waves propagate in the direction of B_0 and opposite direction, with a (phase) velocity

$$V_A = \frac{B_0}{\rho\mu_0}$$

which also the group velocity (no dispersion) In the core, inertial and Alfvén waves are present!

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

A few thoughts

- we expect progress from computer power: large Ra, very different diffusivities
- we still need some experiments
- we need more thoughts on convection models: compressibility, (weak) turbulence models
- we need better knowledge of α , σ , k
- debate between internal or external origin of forces driving inner core convection

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00
