# Bounded functions on the character variety 

Konstantin Ardakov and Laurent Berger

With an appendix by Dragoș Crișan and Jingjie Yang

#### Abstract

This paper is motivated by an open question in $p$-adic Fourier theory, that seems to be more difficult than it appears at first glance. Let $L$ be a finite extension of $\mathbb{Q}_{p}$ with ring of integers $o_{L}$ and let $\mathbb{C}_{p}$ denote the completion of an algebraic closure of $\mathbb{Q}_{p}$. In their work on $p$-adic Fourier theory, Schneider and Teitelbaum defined and studied the character variety $\mathfrak{X}$. This character variety is a rigid analytic curve over $L$ that parameterizes the set of locally $L$-analytic characters $\lambda:\left(o_{L},+\right) \rightarrow\left(\mathbb{C}_{p}^{\times}, \times\right)$. One of the main results of Schneider and Teitelbaum is that over $\mathbb{C}_{p}$, the curve $\mathfrak{X}$ becomes isomorphic to the open unit disk. Let $\Lambda_{L}(\mathfrak{X})$ denote the ring of bounded-by-one functions on $\mathfrak{X}$. If $\mu \in o_{L} \llbracket o_{L} \rrbracket$ is a measure on $o_{L}$, then $\lambda \mapsto \mu(\lambda)$ gives rise to an element of $\Lambda_{L}(\mathfrak{X})$. The resulting map $o_{L} \llbracket o_{L} \rrbracket \rightarrow \Lambda_{L}(\mathfrak{X})$ is injective. The question is: do we have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ ?

In this paper, we prove various results that were obtained while studying this question. In particular, we give several criteria for a positive answer to the above question. We also recall and prove the "Katz isomorphism" that describes the dual of a certain space of continuous functions on $o_{L}$. An important part of our paper is devoted to providing a proof of this theorem which was stated in 1977 by Katz. We then show how it applies to the question. Besides p-adic Fourier theory, the above question is related to the theory of formal groups, the theory of integer valued polynomials on $o_{L}, p$-adic Hodge theory, and Iwasawa theory.

## 1. Introduction

1.1. Motivation. Let $L$ be a finite extension of $\mathbb{Q}_{p}$ and let $\mathbb{C}_{p}$ denote the completion of an algebraic closure of $\mathbb{Q}_{p}$. In their work on $p$-adic Fourier theory [28], Schneider and Teitelbaum defined and studied the character variety $\mathfrak{X}$. This character variety is a rigid analytic curve over $L$ that parameterizes the set of locally $L$-analytic characters $\lambda:\left(o_{L},+\right) \rightarrow\left(\mathbb{C}_{p}^{\times}, \times\right)$. One of the main results of Schneider and Teitelbaum is that over $\mathbb{C}_{p}$, the curve $\mathfrak{X}$ becomes isomorphic to the open unit disk.

The ring $\mathcal{O}_{L}(\mathfrak{X})$ of holomorphic functions on $\mathfrak{X}$ is a Prüfer domain, with an action of $o_{L}$ coming from the natural action of $o_{L}$ on the set of locally
$L$-analytic characters. One can then localize and complete $\mathcal{O}_{L}(\mathfrak{X})$ in order to obtain the Robba ring $\mathscr{R}_{L}(\mathfrak{X})$, and define $\left(\varphi, o_{L}^{\times}\right)$-modules over that ring and some of its subrings. These objects are defined and studied in [5], with the hope that they will be useful for a generalization of the $p$-adic local Langlands correspondence from $\mathrm{GL}_{2}\left(\mathbb{Q}_{p}\right)$ to $\mathrm{GL}_{2}(L)$.

In this paper, we instead consider a natural subring of $\mathcal{O}_{L}(\mathfrak{X})$, the ring $\Lambda_{L}(\mathfrak{X})$ of functions whose norms are bounded above by 1 . If $\mu \in o_{L} \llbracket o_{L} \rrbracket$ is a measure on $o_{L}$, then $\lambda \mapsto \mu(\lambda)$ gives rise to such a function $\mathfrak{X} \rightarrow \mathbb{C}_{p}$. The resulting map $o_{L} \llbracket o_{L} \rrbracket \rightarrow \Lambda_{L}(\mathfrak{X})$ is injective. We do not know of any example of an element of $\Lambda_{L}(\mathfrak{X})$ that is not in the image of the above map.
Question 1.1.1. Do we have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ ?
This question seems to be more difficult than it appears at first glance, and so far we have not been able to answer it (except of course for $L=\mathbb{Q}_{p}$ ). The results of this paper were obtained while we were studying this problem. A related question is raised in remark 2.5 of [11]. We now give more details about the character variety $\mathfrak{X}$, and then explain our main results.
1.2. The character variety. Let $\mathfrak{B}$ denote the open unit disk, seen as a rigid analytic variety. This space naturally parameterizes the set of locally $\mathbb{Q}_{p}$-analytic characters $\lambda:\left(\mathbb{Z}_{p},+\right) \rightarrow\left(\mathbb{C}_{p}^{\times}, \times\right)$. Indeed, if $K$ is a closed subfield of $\mathbb{C}_{p}$ and $z \in \mathfrak{m}_{K}=\mathfrak{B}(K)$, then the map $\lambda_{z}: a \mapsto(1+z)^{a}$ is a $K$-valued locally $\mathbb{Q}_{p}$-analytic character on $\mathbb{Z}_{p}$, and every such character arises in this way. Note that $\lambda_{z}^{\prime}(0)=\log (1+z)$. If $d=\left[L: \mathbb{Q}_{p}\right]$, then $o_{L} \simeq \mathbb{Z}_{p}^{d}$ and hence $\mathfrak{B}^{d}$ parameterizes the set of locally $\mathbb{Q}_{p}$-analytic characters $\lambda:\left(o_{L},+\right) \rightarrow$ $\left(\mathbb{C}_{p}^{\times}, \times\right)$. Such a character is locally $L$-analytic if and only if $\lambda^{\prime}(0)$ is $L$-linear. In coordinates $z=\left(z_{1}, \ldots, z_{d}\right)$, there exists $\alpha_{2}, \ldots, \alpha_{d} \in L$ such that the character corresponding to $z$ is locally $L$-analytic if and only if $\log \left(1+z_{i}\right)=\alpha_{i} \cdot \log \left(1+z_{1}\right)$ for all $i=2, \ldots, d$. These $d-1$ Cauchy-Riemann equations cut out the character variety $\mathfrak{X}$ inside $\mathfrak{B}^{d}$. Schneider and Teitelbaum showed [28] that $\mathfrak{X}$ is a smooth rigid analytic group curve over $L$.

The ring of $\mathbb{Q}_{p}$-analytic distributions $D^{\mathbb{Q}_{p}-\text { an }}\left(o_{L}, L\right)$ on $o_{L}$ is isomorphic to the ring of power series in $d$ variables that converge on the open unit polydisk. Every distribution $\mu \in D^{\mathbb{Q}_{p}-\text { an }}\left(o_{L}, L\right)$ gives rise to an element of $\mathcal{O}_{L}(\mathfrak{X})$, defined by the map $\lambda \mapsto \mu(\lambda)$. This gives rise to a surjective (but not injective if $\left.L \neq \mathbb{Q}_{p}\right) \operatorname{map} D^{\mathbb{Q}_{p}-\text { an }}\left(o_{L}, L\right) \rightarrow \mathcal{O}_{L}(\mathfrak{X})$, whose restriction to $o_{L} \llbracket o_{L} \rrbracket$ is injective and has image contained in $\Lambda_{L}(\mathfrak{X})$.
1.3. Schneider and Teitelbaum's uniformization. We now explain why over $\mathbb{C}_{p}$, the curve $\mathfrak{X}$ becomes isomorphic to the open unit disk. Let $G_{L}=$ $\operatorname{Gal}\left(\overline{\mathbb{Q}}_{p} / L\right)$. Choose a uniformizer $\pi$ of $o_{L}$ and let $\mathcal{G}$ denote the Lubin-Tate formal group attached to $\pi$. This gives us a Lubin-Tate character $\chi_{\pi}: G_{L} \rightarrow$ $o_{L}^{\times}$and, once we have chosen a coordinate $Z$ on $\mathcal{G}$, a formal addition law $X \oplus Y \in o_{L} \llbracket X, Y \rrbracket$, endomorphisms $[a](Z) \in o_{L} \llbracket Z \rrbracket$ for all $a \in o_{L}$, and a logarithm $\log _{\mathrm{LT}}(Z) \in L \llbracket Z \rrbracket$.

By the work of Tate on $p$-divisible groups, there is a non-trivial homomorphism $\mathcal{G} \rightarrow \mathbf{G}_{\mathrm{m}}$ defined over $o_{\mathbb{C}_{p}}$. Concretely, there exists a power series $G(Z) \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket$ (where $G(Z)$ is a generator of $\operatorname{Hom}_{o_{C_{p}}}\left(\mathcal{G}, \mathbf{G}_{\mathrm{m}}\right)$ ) such that $(1+G(X \oplus Y))=(1+G(X)) \cdot(1+G(Y))$. If $z \in \mathfrak{m}_{\mathbb{C}_{p}}$, then the map $\lambda_{z}: a \mapsto 1+G([a](z))$ is a locally $L$-analytic character on $o_{L}$, and every such character arises in this way. This explains the main idea behind the proof of the statement that over $\mathbb{C}_{p}$, the curve $\mathfrak{X}$ becomes isomorphic to the open unit disk.

In particular, $\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$ is isomorphic to the ring of power series $\sum_{i \geq 0} a_{i} Z^{i}$ with $a_{i} \in \mathbb{C}_{p}$ that converge on the open unit disk. Let $\chi_{\text {cyc }}$ denote the cyclotomic character, and let $\tau: G_{L} \rightarrow o_{L}^{\times}$denote the character $\tau=\chi_{\text {cyc }}$. $\chi_{\pi}^{-1}$. The Galois group $G_{L}$ acts on $\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$ by the formula $g\left(\sum_{i \geq 0} a_{i} Z^{i}\right)=$ $\sum_{i \geq 0} g\left(a_{i}\right)\left[\tau(g)^{-1}\right](Z)^{i}$. This action is called the twisted Galois action, and we write $G_{L}, *$ to recall the twist. It follows from the Ax-Sen-Tate theorem that $\mathbb{C}_{p}^{G_{L}}=L$ and then, by unravelling the definitions, that $\mathcal{O}_{L}(\mathfrak{X})=\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})^{G_{L}, *}$. At the level of bounded functions, this tells us that $\Lambda_{L}(\mathfrak{X})=o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{G_{L}, *}$. The natural map $o_{L} \llbracket o_{L} \rrbracket \rightarrow \Lambda_{L}(\mathfrak{X})$ sends, for instance, the Dirac measure $\delta_{a}$ with $a \in o_{L}$ to $1+G([a](Z)) \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{G_{L}, *}$.
1.4. The operators $\varphi_{q}, \psi_{q}$. The monoid $\left(o_{L}, \times\right)$ acts on $o_{L}$ by multiplication, and hence on the set of locally $L$-analytic characters, on $\mathfrak{X}$, and on the ring $\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$. If $a \in o_{L}$, this action is given by $f(Z) \mapsto f([a](Z))$. Let $q$ denote the cardinality of the residue field $k_{L}$ of $o_{L}$ and let $\varphi_{q}$ denote the action of $\pi$ on $\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$. The map $\varphi_{q}$ is injective and the ring $\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$ is a free $\varphi_{q}\left(\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})\right)$-module of rank $q$. Let $\psi_{q}: \mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X}) \rightarrow \mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$ be the map defined by $\varphi_{q}\left(\psi_{q}(f(Z))\right)=1 / q \cdot \operatorname{Tr}_{\mathcal{C}_{p}(\mathfrak{X}) / \varphi_{q}\left(\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})\right)}(f(Z))$. The action of $o_{L}$ and the operator $\psi_{q}$ commute with the twisted action of $G_{L}$, and therefore preserve $\mathcal{O}_{L}(\mathfrak{X})$. If we consider the image of the map $D^{\mathbb{Q}_{p}-\text { an }}\left(o_{L}, L\right) \rightarrow \mathcal{O}_{L}(\mathfrak{X})$, we have $a \cdot \delta_{b}=\delta_{a b}$ and $\psi_{q}\left(\delta_{b}\right)=0$ if $b \in o_{L}^{\times}$and $\psi_{q}\left(\delta_{b}\right)=\delta_{b / \pi}$ if $b \in \pi o_{L}$. In particular, $o_{L} \llbracket o_{L} \rrbracket{ }^{\psi_{q}=0}$ coincides with $o_{L} \llbracket o_{L}^{\times} \rrbracket$, those measures that are supported in $o_{L}^{\times}$. We use later on the fact (Lemma 5.1.9) that $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if $\Lambda_{L}(\mathfrak{X})^{\psi_{q}=0}=o_{L} \llbracket o_{L}^{\times} \rrbracket$. Note that if $L \neq \mathbb{Q}_{p}$, then $\psi_{q}\left(\Lambda_{\mathbb{C}_{p}}(\mathfrak{X})\right)$ is not contained in $\Lambda_{\mathbb{C}_{p}}(\mathfrak{X})$ as $\operatorname{Tr}_{\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X}) / \varphi_{q}\left(\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})\right)}(f(Z))$ is divisible by $\pi$, but not always by $q$. Our first result is the following.

Theorem 1.4.1. We have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if $\psi_{q}\left(\Lambda_{L}(\mathfrak{X})\right) \subset \Lambda_{L}(\mathfrak{X})$.
This is proved at the end of $\S 3.1$.
1.5. The polynomials $P_{n}$. Recall that $G(Z)$ is a generator of $\operatorname{Hom}_{o_{C_{p}}}\left(\mathcal{G}, \mathbf{G}_{\mathrm{m}}\right)$ and that $\tau=\chi_{\text {cyc }} \cdot \chi_{\pi}^{-1}$. In fact, we have $G(Z)=\exp \left(\Omega \cdot \log _{\mathrm{LT}}(Z)\right)-1=\Omega \cdot Z+$ $\mathrm{O}\left(Z^{2}\right)$, where $\Omega$ is a certain special element of $\mathfrak{m}_{\mathbb{C}_{p}}$ such that $g(\Omega)=\tau(g) \cdot \Omega$. In particular, for all $n \geq 0$, there exists a polynomial $P_{n}(Y) \in L[Y]$ such that $1+G(Z)=\sum_{n \geq 0} P_{n}(\Omega) \cdot Z^{n}$. For $n \geq 0$, the polynomial $P_{n}(Y)$ is of degree $n$, and its leading coefficient is $1 / n!$. For example, assume that the
coordinate $Z$ is chosen in a way that $\log _{\mathrm{LT}}(Z)=\sum_{k \geq 0} Z^{q^{k}} / \pi^{k}$. Then we have (see Proposition 4.3.1 for more details)

$$
P_{n}(Y)=\sum_{n_{0}+q n_{1}+\cdots+q^{d} n_{d}=n} \frac{Y^{n_{0}+\cdots+n_{d}}}{n_{0}!\cdots n_{d}!\cdot \pi^{1 \cdot n_{1}+2 \cdot n_{2}+\cdots+d \cdot n_{d}}}
$$

If $a \in o_{L}$, then $G([a](Z))=\sum_{n \geq 1} P_{n}(\Omega) \cdot[a](Z)^{n}=\sum_{n \geq 1} P_{n}(a \Omega) \cdot Z^{n}$. This implies for instance that $P_{n}(a \Omega) \in o_{\mathbb{C}_{p}}$ for all $a \in o_{L}$. For $n \geq 0$ and $i \geq n$, let $\sigma_{n, i}(Y) \in L[Y]$ denote the polynomials such that $[a](Z)^{n}=\sum_{i \geq n} \sigma_{n, i}(a) Z^{i}$ for all $a \in o_{L}$. The $\sigma_{n, i}(Y)$ are all elements of Int, the $o_{L}$-submodule of $L[Y]$ of integer valued polynomials on $o_{L}$. The fact that $\sum_{n \geq 0} P_{n}(\Omega) \cdot[a](Z)^{n}=$ $\sum_{n \geq 0} P_{n}(a \Omega) \cdot Z^{n}$ implies that $P_{n}(a \Omega)=\sum_{i=0}^{n} \sigma_{i, n}(a) P_{i}(\Omega)$.

If $\mu \in D^{\mathbb{Q}_{p}-\text { an }}\left(o_{L}, L\right)$, its image in $\mathcal{O}_{L}(\mathfrak{X})$ is therefore $f_{\mu}(Z)=\sum_{n \geq 0} Z^{n}$. $\sum_{i=0}^{n} \mu\left(\sigma_{i, n}\right) P_{i}(\Omega)$. Let Pol denote the $o_{L}$-span of the $\sigma_{n, i}(Y)$ inside $L[Y]$, so that $\mathrm{Pol} \subset \mathrm{Int}$. The following gives a relation between our question and the theory of integer valued polynomials ([30], [31]):

Theorem 1.5.1. If $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$, then $\mathrm{Pol}=$ Int.
The proof can be found at the end of $\S 4.2$. The converse statement is not true, but " $\mathrm{Pol}=\mathrm{Int}$ " is equivalent to $U \llbracket Z \rrbracket^{G_{L}, *}=o_{L} \llbracket o_{L} \rrbracket$, where $U$ is the $o_{L^{-}}$ submodule of $o_{\mathbb{C}_{p}}$ generated by $\left\{P_{n}(\Omega)\right\}_{n \geq 0}$. We have not been able to prove that $\mathrm{Pol}=\mathrm{Int}$, although we can show that Pol is $p$-adically dense in Int. Some numerical evidence indicates that $\mathrm{Pol}=$ Int seems to hold: the details can be found in the Appendix by D. Crisan and J. Yang at the end of our paper.

We now explain how to compute the valuation of $P_{n}(\Omega)$ for certain $n$. The elements $z \in \mathfrak{m}_{\mathbb{C}_{p}}$ such that $G(z)=0$ correspond to those locally $L$-analytic characters $\lambda_{z}$ such that $\lambda_{z}(1)=1$. Being locally $L$-analytic, they are necessarily trivial on an open subgroup of $o_{L}$, and correspond to certain torsion points of $\mathcal{G}$. We know the valuations of these torsion points, and this way we can determine the Newton polygon of $G(Z)$. Using this idea, we can prove the following. Let $e$ be the ramification index of $L / \mathbb{Q}_{p}$. If $m \geq 0$, let $k_{m}=\lfloor(m-1) / e\rfloor$, so that $m=e k_{m}+r$ with $1 \leq r \leq e$. For $m \geq 0$, let $x_{m}=q^{m} / p^{k_{m}+1}$ (so that $x_{0}=1$ and $\left.x_{1}=q / p\right)$. Write $m=e n+r$ and let

$$
y_{0}=\frac{e}{p-1}-\frac{1}{q-1} \text { and } y_{m}=\frac{e}{p^{n}(p-1)}-\frac{r}{p^{n+1}}-\frac{1}{(q-1) p^{n+1}}
$$

Theorem 1.5.2. For all $m \geq 0$, we have $\operatorname{val}_{\pi}\left(P_{x_{m}}(\Omega)\right)=y_{m}$.
For example, if $L=\mathbb{Q}_{p^{2}}$, then $\operatorname{val}_{p}\left(P_{p^{k}}(\Omega)\right)=1 / p^{k-1}(q-1)$ for all $k \geq 0$.

### 1.6. Galois-continuous functions and the Katz map. Following Katz

 [19], we let $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$ denote the $o_{L}$-module of Galois-continuous functions, namely those continuous functions $f: o_{L} \rightarrow o_{\mathbb{C}_{p}}$ such that $g(f(a))=f(\tau(g) \cdot a)$ for all $a \in o_{L}$ and $g \in G_{L}$. If $P(T) \in L[T]$, then $a \mapsto P(a \cdot \Omega)$ is such a function. Let $K$ be a closed subfield of $\mathbb{C}_{p}$ containing $L$. The dual Katz map is the map $\mathcal{K}^{*}: \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), o_{K}\right) \rightarrow o_{K} \llbracket Z \rrbracket$ given by $\mu \mapsto \sum_{n \geq 0} \mu\left(P_{n}\right) \cdot Z^{n}$. Let$o_{K} \llbracket Z \rrbracket \psi_{q}$-int denote the set of $f(Z) \in o_{K} \llbracket Z \rrbracket$ such that $\psi_{q}^{n}(f(Z)) \in o_{K} \llbracket Z \rrbracket$ for all $n \geq 1$. Our main technical result is the following
Theorem 1.6.1. Suppose that $L=\mathbb{Q}_{p^{2}}$.
(1) The map $\mathcal{K}^{*}: \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), o_{K}\right) \rightarrow o_{K} \llbracket Z \rrbracket$ is injective.
(2) Its image is equal to $o_{K} \llbracket Z \rrbracket^{\psi_{q}-\mathrm{int}}$.

An important part of our paper is devoted to providing a proof of this theorem, which is completed at the end of $\S 3.6$. We note that Theorem 1.6.1 was stated by Katz at [19, p. 60], but he did not give a proof. The remarks contained in the last paragraph of $[19, \S I V]$ seem to indicate that his proof is different to ours.

The hardest part of the theorem is the claim concerning the image of $\mathcal{K}^{*}$. Note that when $L=\mathbb{Q}_{p^{2}}$, the dual of the $p$-divisible group attached to $\mathcal{G}$ has dimension 1. Using this and Theorem 1.5.2 for $L=\mathbb{Q}_{p^{2}}$, we can prove (see Proposition 3.6.5) that every element of $o_{\infty}=o_{\mathbb{C}_{p}}^{\text {ker } \tau}$ can be written as $\sum_{n \geq 0} \lambda_{n} \cdot P_{n}(\Omega)$ where $\lambda_{n} \in o_{L}$ and $\lambda_{n} \rightarrow 0$. This important ingredient of the proof of Theorem 1.6.1 is not known to be available if $L \neq \mathbb{Q}_{p^{2}}$.
1.7. Applications of the Katz isomorphism. Throughout this section, we assume that $L=\mathbb{Q}_{p^{2}}$ and $\pi=p$, so that $\mathcal{K}^{*}: \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), o_{K}\right) \rightarrow$ $o_{K} \llbracket Z \rrbracket^{\psi_{q} \text {-int }}$ is an isomorphism. Let $L_{\infty}=\mathbb{C}_{p}^{\mathrm{ker} \tau}$ and $o_{\infty}=o_{\mathbb{C}_{p}}^{\mathrm{ker} \tau}$. Since $\pi=p$, $L_{\infty}$ is also the completion of $L\left(\mathcal{G}\left[p^{\infty}\right]\right)$.

Theorem 1.6.1 gives us an isomorphism $\mathcal{K}^{*}: \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right), o_{K}\right) \rightarrow$ $o_{K} \llbracket Z \rrbracket \psi_{q}=0$, and we have a natural isomorphism $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right) \rightarrow o_{\infty}$. Applying this to $K=L$, we get the following result (Theorem 5.1.4), where $o_{\infty}^{*}=$ $\operatorname{Hom}_{o_{L}}\left(o_{\infty}, o_{L}\right)$ :
Theorem 1.7.1. The map $\mathcal{K}^{*}$ gives rise to an isomorphism $o_{\infty}^{*} \simeq o_{L} \llbracket Z \rrbracket^{\psi_{q}=0}$.
Let $\Gamma_{L}^{\mathrm{LT}}=\operatorname{Gal}\left(L\left(\mathcal{G}\left[p^{\infty}\right]\right) / L\right)$ and $\Gamma_{\mathbb{Q}_{p}}^{\mathrm{cyc}}=\operatorname{Gal}\left(\mathbb{Q}_{p}\left(\mu_{p^{\infty}}\right) / \mathbb{Q}_{p}\right)$. In the cyclotomic setting, Perrin-Riou showed [25, Lemma 1.5] that $\mathbb{Z}_{p} \llbracket Z \rrbracket^{\psi_{p}=0}$ is a free $\mathbb{Z}_{p} \llbracket \Gamma_{\mathbb{Q}_{p}}^{c y c} \rrbracket$-module of rank 1 . She also raised the question of what happens in the present setting. Using Theorem 1.7.1, we show in Corollary 5.2.12 that $o_{L} \llbracket Z \rrbracket^{\psi_{q}=0}$ is in fact not a free $o_{L} \llbracket \Gamma_{L}^{\mathrm{LT}} \rrbracket$-module of rank 1 .

We can also apply the isomorphism $\operatorname{Hom}_{o_{L}}\left(o_{\infty}, o_{K}\right) \simeq o_{K} \llbracket Z \rrbracket^{\psi_{q}=0}$ to $K=$ $L_{\infty}$, and we get $\operatorname{Hom}_{o_{L}}\left(o_{\infty}, o_{\infty}\right) \simeq o_{\infty} \llbracket Z \rrbracket^{\psi_{q}=0}$. The natural action of $G_{L}$ on the left is the twisted Galois action on the right. Since $\Lambda_{L}(\mathfrak{X})=o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{G_{L}, *}=$ $o_{\infty} \llbracket Z \rrbracket^{G_{L}, *}$, we get the following result (Theorem 5.1.6):
Theorem 1.7.2. We have $\operatorname{End}_{o_{L}}^{G_{L}}\left(o_{\infty}\right) \simeq \Lambda_{L}(\mathfrak{X})^{\psi_{q}=0}$.
Recall that $o_{L} \llbracket o_{L}^{\times} \rrbracket \subset \Lambda_{L}(\mathfrak{X})^{\psi_{q}=0}$. If $a \in o_{L}^{\times}$, then $\delta_{a} \in o_{L} \llbracket o_{L}^{\times} \rrbracket$ acts on $o_{\infty}$ by an element $g \in G_{L}$ such that $\tau(g)=a$. Since $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if $\Lambda_{L}(\mathfrak{X})^{\psi_{q}=0}=o_{L} \llbracket o_{L}^{\times} \rrbracket$, we get the following criterion (Theorem 5.1.8):
Theorem 1.7.3. We have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if every continuous $L$ linear and $G_{L}$-equivariant map $f: L_{\infty} \rightarrow L_{\infty}$ comes from the Iwasawa algebra $L \otimes_{o_{L}} o_{L} \llbracket \Gamma_{L}^{\mathrm{LT}} \rrbracket$.

In the cyclotomic case, Tate's normalized trace maps $T_{n}: \mathbb{Q}_{p}^{\text {cyc }} \rightarrow \mathbb{Q}_{p}\left(\mu_{p^{n}}\right)$ are examples of continuous $\mathbb{Q}_{p}$-linear and $G_{\mathbb{Q}_{p}}$-equivariant maps $f: \mathbb{Q}_{p}^{\text {cyc }} \rightarrow$ $\mathbb{Q}_{p}^{\text {cyc }}$ that do not come from the Iwasawa algebra $L \otimes_{o_{L}} o_{L} \llbracket \Gamma_{\mathbb{Q}_{p}}^{\text {cyc }} \rrbracket$. The lack of normalized trace maps in the Lubin-Tate setting is a source of many complications. In his PhD thesis, Fourquaux considered continuous $L$-linear and $G_{L}$-equivariant maps $f: L_{\infty} \rightarrow L_{\infty}$. We generalize some of Fourquaux's results: we prove in Proposition 5.1.13 that if $f \neq 0$ is such a map, then there exists $n \geq 0$ such that $f\left(L_{\infty}\right)$ contains a basis of the $L_{n}$-vector space $L_{n}[\log \Omega]$, where $L_{n}=L\left(\mathcal{G}\left[p^{n}\right]\right)$. In particular, $f$ necessarily has a very large image, so there can be no analogue of the equivariant trace maps $T_{n}$.

The Katz isomorphism also allows us to prove several results about the span of the polynomials $P_{n}$ in $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$. Recall that by [28, Theorem 4.7], every Galois-continuous locally analytic function on $o_{L}$ can be expanded as an overconvergent series in the $P_{n}$. One may then wonder about the existence of such an expansion for Galois-continuous functions. Let $\mathcal{C}^{0}(L)$ denote the set of sequences $\left\{\lambda_{n}\right\}_{n \geq 0}$ with $\lambda_{n} \in L$ and $\lambda_{n} \rightarrow 0$. The Katz isomorphism, and computations involving $\psi_{q}$, imply the following (Proposition 5.3.1, Corollary 5.3.4, and Corollary 5.3.9):

Theorem 1.7.4. The map $\mathcal{C}^{0}(L) \rightarrow \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$, given by

$$
\left\{\lambda_{n}\right\}_{n \geq 0} \mapsto\left[a \mapsto \sum_{n=0}^{\infty} \lambda_{n} \cdot P_{n}(a \Omega)\right]
$$

is injective, has dense image, but is not surjective.
The same methods imply the following precise estimates for those elements of $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ that are given by a polynomial function $a \mapsto Q(a \Omega)$ with $Q(T) \in L[T]$. See Proposition 5.3.6 and Corollary 5.3.12.

Theorem 1.7.5. Assume that $Z$ is a coordinate on $\mathcal{G}$ such that $[p](Z)=$ $Z^{q}+p Z$. Let $Q(T) \in L[T]$ be a polynomial such that $Q(a \Omega) \in o_{\mathbb{C}_{p}}$ for all $a \in o_{L}$, and write $Q(T)=\sum_{n=0}^{\operatorname{deg} Q} \lambda_{n} \cdot P_{n}(T)$.
(1) We have $\lambda_{n} \in p^{-k} o_{L}$ if $n \leq q^{k}$.
(2) For all $k$, there exists such a polynomial $Q$ for which $\lambda_{q^{k}-1}=p^{-k}$.
1.8. Other criteria. The following two criteria for our main question may be of interest.

Let $\partial: \mathbb{C}_{p} \llbracket Z \rrbracket \rightarrow \mathbb{C}_{p} \llbracket Z \rrbracket$ denote the invariant derivative $\partial=\log _{\mathrm{LT}}^{\prime}(Z)^{-1}$. $d / d Z$. It does not commute with the twisted action of $G_{L}$, but $D=\Omega^{-1} \cdot \partial$ does. We get a map $D: \mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X}) \rightarrow \mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$ that does not preserve $\Lambda_{\mathbb{C}_{p}}(\mathfrak{X})$ if $L \neq \mathbb{Q}_{p}$ since $\operatorname{val}_{p}\left(\Omega^{-1}\right)<0$. Note that $D\left(\delta_{a}\right)=a \cdot \delta_{a}$ if $a \in o_{L}$, so that $D$ does preserve $o_{L} \llbracket o_{L} \rrbracket$. We have the following result.

Theorem 1.8.1. If $L=\mathbb{Q}_{p^{2}}$, then $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if we have $D^{q-1}\left(\Lambda_{L}(\mathfrak{X})\right) \subset \Lambda_{L}(\mathfrak{X})$.

This Theorem follows from Theorem 1.4.1 and the following result, which is inspired by computations of Katz: assume that $L=\mathbb{Q}_{p^{2}}$ and that $\pi=p$. Let $\lambda=\Omega^{q-1} / p(q-1)!\in o_{\mathbb{C}_{p}}^{\times}$. If $f(Z) \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket$, then

$$
\varphi \psi_{q}(f)-\lambda \cdot D^{q-1}(f) \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket .
$$

Here is another result concerning our main question. It says that if the answer is yes for a finite extension $L / K$, then the answer is also yes for $K$.

Theorem 1.8.2. If $L / K$ is finite and if $\Lambda_{L}\left(\mathfrak{X}_{L}\right)=o_{L} \llbracket o_{L} \rrbracket$, then $\Lambda_{K}\left(\mathfrak{X}_{K}\right)=$ $o_{K} \llbracket o_{K} \rrbracket$.
1.9. Acknowledgements. This paper grew out of a project started with Peter Schneider. The authors are very grateful to him for numerous discussions, interesting insights (in particular, considering the Katz isomorphism), and several invitations to Münster. Several results in this paper were obtained in collaboration with him. L.B. also thanks Pierre Colmez for some discussions about the main problem of this paper.

## 2. The character variety

2.1. Notation. Let $\mathbb{Q}_{p} \subseteq L \subset \mathbb{C}_{p}$ be a field of finite degree $d$ over $\mathbb{Q}_{p}, o_{L}$ the ring of integers of $L, \pi \in o_{L}$ a fixed prime element, $k_{L}=o_{L} / \pi o_{L}$ the residue field, $q:=\left|k_{L}\right|$ and $e$ the absolute ramification index of $L$. We always use the absolute value $\left|\mid\right.$ on $\mathbb{C}_{p}$ which is normalized by $| p \mid=p^{-1}$. We let $G_{L}:=\operatorname{Gal}(\bar{L} / L)$ denote the absolute Galois group of $L$. Throughout our coefficient field $K$ is a complete intermediate extension $L \subseteq K \subseteq \mathbb{C}_{p}$.
2.2. The $p$-adic Fourier transform. We are interested in the character variety $\mathfrak{X}$ of the $L$-analytic commutative group $\left(o_{L},+\right)$. We refer to $[28, \S 2]$ for a precise definition, but recall that $\mathfrak{X}$ is a rigid analytic variety defined over $L$, whose set of $K$-points (for $K$ a field extension of $L$ complete with respect to a non-archimedean absolute value extending the one on $L$ ) is the group $\mathfrak{X}(K)$ of $K$-valued characters $\chi:\left(o_{L},+\right) \rightarrow\left(K^{\times}, \times\right)$that are also $L$-analytic functions:

$$
\mathfrak{X}(K):=\left\{f \in C^{L-\mathrm{an}}\left(o_{L}, K\right): f(a+b)=f(a) f(b) \quad \text { for all } a, b \in o_{L}\right\} .
$$

Here $C^{L-\mathrm{an}}\left(o_{L}, K\right)$ is the space of locally $L$-analytic $K$-valued functions on $o_{L}$. Let $D^{L-a n}\left(o_{L}, K\right)$ be the $K$-algebra of locally $L$-analytic distributions on $o_{L}$, defined in $[29, \S 2]$. One of the main results of $p$-adic Fourier Theory [28, Theorem 2.3] - tells us that there is a canonical isomorphism

$$
\mathcal{F}: D^{L-\mathrm{an}}\left(o_{L}, K\right) \rightarrow \mathcal{O}\left(\mathfrak{X} \times_{L} K\right)
$$

called the $p$-adic Fourier Transform. This isomorphism is determined by

$$
\mathcal{F}(\lambda)(\chi)=\lambda(\chi) \quad \text { for all } \quad \lambda \in D^{L-\mathrm{an}}\left(o_{L}, K\right), \chi \in \mathfrak{X}(K)
$$

Since $\mathfrak{X}$ is a rigid $L$-analytic variety, we have at our disposal the subalgebra $\mathcal{O}^{\circ}(\mathfrak{X})$ of $\mathcal{O}(\mathfrak{X})$ consisting of globally-defined, rigid analytic functions on $\mathfrak{X}$ that are power-bounded - see $[7, \S 1.2 .5]$.

Definition 2.2.1. Write $\Lambda(\mathfrak{X}):=\mathcal{O}^{\circ}(\mathfrak{X})$.
The functorial definition of the character variety does not shed much light on its internal structure. It turns out that the base change $\mathfrak{X} \times{ }_{L} K$ is isomorphic to the rigid analytic open unit disc over $K$, provided the field $K$ is large enough. This isomorphism is obtained with the help of Lubin-Tate formal groups and their associated $p$-divisible groups.
2.3. Lubin-Tate formal groups. Let $Z$ be an indeterminate and let

$$
\mathscr{F}_{\pi}:=\left(\pi Z+Z^{2} o_{L} \llbracket Z \rrbracket\right) \cap\left(Z^{q}+\pi o_{L} \llbracket Z \rrbracket\right)
$$

be the set of possible Frobenius power series. Recall [21, Theorem 8.1.1] ${ }^{1}$ that for every Frobenius power series $\varphi(Z) \in \mathscr{F}_{\pi}$, there is a unique formal group law $F_{\varphi(Z)}=Z_{1} \oplus Z_{2} \in o_{L} \llbracket Z_{1}, Z_{2} \rrbracket$ such that $\varphi(Z)$ is an endomorphism of $F_{\varphi(Z)}$. Since we have fixed a coordinate $Z$ on the power series ring $o_{L} \llbracket Z \rrbracket$, this formal group law defines a formal group $^{2}(\mathcal{G}, \oplus)$ on the underlying formal affine scheme $\operatorname{Spf} o_{L} \llbracket Z \rrbracket$, where we give $o_{L} \llbracket Z \rrbracket$ the $Z$-adic topology. This formal group is called a Lubin-Tate formal group. Up to isomorphism of formal groups, it does not depend on the choice of the Frobenius power series $\varphi(Z)$, however it does depend on the choice of $\pi$. The base change of $\mathcal{G}$ to the completion $\widehat{L^{\text {ur }}}$ of the maximal unramified extension $L^{\text {ur }}$ of $L$ does not even depend on the choice of $\pi$.

The Lubin-Tate formal group $\mathcal{G}$ is in fact a formal $o_{L}$-module. This means that there is a ring homomorphism $o_{L} \rightarrow \operatorname{End}(\mathcal{G}), a \mapsto[a](Z) \in o_{L} \llbracket Z \rrbracket$, such that $[a](Z) \equiv a Z \bmod Z^{2} o_{L} \llbracket Z \rrbracket$ for all $a \in o_{L}$. In other words, the formal group $\mathcal{G}$ admits an action of $o_{L}$ by endomorphisms of formal groups, in such a way that the differential of this action at the identity element 1 of $\mathcal{G}$ agrees with the natural $o_{L}$-action on the cotangent space of $\mathcal{G}$ at 1 . The action of $\pi \in o_{L}$ is given by the power series $[\pi](Z)=\varphi(Z)$.
2.4. A review of $p$-divisible groups. In his seminal paper [32], Tate introduced $p$-divisible groups and considered their relation to formal groups. Here we review some of his fundamental theorems.

Let $R$ be a commutative base ring and let $\Gamma=(\operatorname{Spf} \mathcal{A}, *)$ be a commutative formal group over $R$ where $\mathcal{A}=R \llbracket X_{1}, \cdots, X_{d} \rrbracket$ is a power series ring in $d$ variables over $R$. Then we can associate with $\Gamma$ the $p$-divisible group $\Gamma(p)=$ $\left(\Gamma(p)_{n}, i_{n}\right)$ over $R$ where $\Gamma(p)_{n}:=\Gamma\left[p^{n}\right]$ is the subgroup of elements of $\Gamma$ killed by $p^{n}$. More precisely, let $\psi: \mathcal{A} \rightarrow \mathcal{A}$ be the continuous $R$-algebra homomorphism which corresponds to multiplication by $p$ on $\Gamma$ and let $J_{n}$ be the ideal $\mathcal{A} \psi^{n}\left(X_{1}\right)+\cdots+\mathcal{A} \psi^{n}\left(X_{d}\right)$ of $\mathcal{A}$; then $\mathcal{A} / J_{n}$ is a Hopf algebra over $R$ free of finite rank over $R$, and $\Gamma(p)_{n}=\operatorname{Spec}\left(\mathcal{A} / J_{n}\right)$ is the corresponding commutative finite flat group scheme over $R$. The closed immersions $i_{n}: \Gamma(p)_{n} \rightarrow \Gamma(p)_{n+1}$ are obtained from the $R$-algebra surjections $\mathcal{A} / J_{n+1} \rightarrow \mathcal{A} / J_{n}$.

[^0]Theorem 2.4.1 (§2.2, Proposition 1 [32]). Let $R$ be a complete Noetherian local ring whose residue field $k$ is of characteristic $p>0$. Then $\Gamma \mapsto \Gamma(p)$ is an equivalence between the category of divisible commutative formal groups over $R$ and the category of connected $p$-divisible groups over $R$.

Recall that the formal group $\Gamma$ is said to be divisible if $\mathcal{A} / J_{1}$ is finitely generated as an $R$-module, and a $p$-divisble group $\left(\Gamma_{n}, i_{n}\right)$ is said to be connected if every finite flat group scheme $\Gamma_{n}$ is a connected scheme.

Remark 2.4.2. The fact that the functor $\Gamma \mapsto \Gamma(p)$ is fully faithful holds in greater generality: if $R$ is any commutative ring and $G, H$ are divisible formal groups defined over $R$ such that $\mathcal{O}(G)$ and $\mathcal{O}(H)$ are power series rings in finitely many variables over $R$, then the natural map

$$
\operatorname{Hom}_{R-\mathrm{fgp}}(G, H) \rightarrow \operatorname{Hom}_{p-\mathrm{div}}(G(p), H(p))
$$

is a bijection.
Now we specialise to the case where $R$ is our complete discrete valuation ring $o_{L}$. The Tate module associated to a $p$-divisible group $\Gamma=\left(\Gamma_{n}, i_{n}\right)$ is by definition

$$
T(\Gamma):=\lim _{\leftrightarrows} \Gamma_{n}(\bar{L})
$$

where $\bar{L}$ is the algebraic closure of $L, \Gamma_{n}(\bar{L})=\operatorname{Hom}_{o_{L}-\operatorname{alg}}\left(\mathcal{O}\left(\Gamma_{n}\right), \bar{L}\right)$ is the set of $\bar{L}$-points of $\Gamma_{n}$, and the connecting maps in the inverse limit are induced by the multiplication-by- $p$-maps $j_{n}: \Gamma_{n+1} \rightarrow \Gamma_{n}$. By functoriality, the Tate module $T(\Gamma)$ carries a natural action of the absolute Galois group $G_{L}=\operatorname{Gal}(\bar{L} / L)$, making $T(\Gamma)$ into a continuous $\mathbb{Z}_{p}$-linear representation of $G_{L}$ of rank equal to the height $h$ of $\Gamma$. Remarkably, it turns out that this Galois representation completely determines the $p$-divisible group $\Gamma$. More precisely, we have the following

Theorem 2.4.3 (§4.2, Corollary 1 [32]). The functor $\Gamma \mapsto T(\Gamma)$ is a fully faithful embedding of the category of p-divisible groups over $o_{L}$ into the category of finite rank $\mathbb{Z}_{p}$-linear continuous representations of $G_{L}$.
2.5. Cartier duality for $p$-divisible groups. The category of commutative finite flat group $R$-schemes admits a duality called Cartier duality: if $G$ is a commutative finite flat group scheme over $R$, then its Cartier dual is defined by $G^{\vee}=\operatorname{Spec}\left(\mathcal{O}(G)^{*}\right)$ where $\mathcal{O}(G)^{*}:=\operatorname{Hom}_{R}(\mathcal{O}(G), R)$ is the $R$-linear dual of the coordinate ring $\mathcal{O}(G)$. The group structure on $G^{\vee}$ is obtained by dualising the multiplication map on $\mathcal{O}(G)$ and the scheme structure on $G^{\vee}$ is obtained by dualising the comultiplication map on $\mathcal{O}(G)$ encoding the group structure on $G$.

Tate shows in $[32, \S 2.3]$ that Cartier duality extends naturally to a duality $\Gamma \mapsto \Gamma^{\vee}$ on the category of $p$-divisible groups. He also shows in [32, §4] that when $R=o_{L}$, the Tate-module functor to Galois representations converts Cartier duality into what is now called Tate duality on Galois representations,
namely $V \mapsto \operatorname{Hom}\left(V, \mathbb{Z}_{p}(1)\right)$. In other words, there is a natural isomorphism of continuous $G_{L}$-representations on finite rank $\mathbb{Z}_{p}$-modules

$$
T\left(\Gamma^{\vee}\right) \cong \operatorname{Hom}_{\mathbb{Z}_{p}}\left(T(\Gamma), \mathbb{Z}_{p}(1)\right)
$$

where $\mathbb{Z}_{p}(1):=T\left(\widehat{\mathbb{G}}_{m}(p)\right)$ is the Tate module associated to the formal multiplicative group $\widehat{\mathbb{G}}_{m}$, the formal completion at the identity of the group scheme $\mathbb{G}_{m}:=\operatorname{Spec} o_{L}\left[T, T^{-1}\right]$.
2.6. The character $\tau: G_{L} \rightarrow o_{L}^{\times}$and the period $\Omega$. We return to the Lubin-Tate formal group $\mathcal{G}$ as in $\S 2.3$, which is easily seen to be divisible. Because $\mathcal{G}$ is a formal $o_{L}$-module, the functoriality of $T(-)$ implies that the Tate module $T(\mathcal{G}(p))$ of the $p$-divisible group $\mathcal{G}(p)$ associated with $\mathcal{G}$ is actually an $o_{L}$-module. It is a fundamental fact due to Lubin and Tate - see [23, Theorem 2] - that $T(\mathcal{G}(p))$ is a free $o_{L}$-module of rank one. Since $o_{L}$ is itself a free $\mathbb{Z}_{p}$-module of $\operatorname{rank} d=\left[L: \mathbb{Q}_{p}\right]$, it follows that the underlying $\mathbb{Z}_{p}$-module of $T\left(\mathcal{G}(p)^{\vee}\right) \cong \operatorname{Hom}_{\mathbb{Z}_{p}}\left(T(\mathcal{G}(p)), \mathbb{Z}_{p}\right)$ is free of rank $d$ as a $\mathbb{Z}_{p}$-module as well. Since it is also an $o_{L}$-module by the functoriality of $\operatorname{Hom}_{\mathbb{Z}_{p}}\left(-, \mathbb{Z}_{p}\right)$, we see that $T\left(\mathcal{G}(p)^{\vee}\right)$ is also a free $o_{L}$-module of rank 1 .

On the way to his proof of Theorem 2.4.3, Tate explains how to compute $T\left(\mathcal{G}(p)^{\vee}\right)$ : using Cartier duality, on [32, p. 177] he obtains a natural isomorphism of abelian groups

$$
\begin{equation*}
T\left(\mathcal{G}(p)^{\vee}\right) \cong \operatorname{Hom}_{p-\operatorname{div} / o_{\mathbb{C}_{p}}}\left(\mathcal{G}(p) \times_{o_{L}} o_{\mathbb{C}_{p}}, \widehat{\mathbb{G}}_{m}(p) \times_{o_{L}} o_{\mathbb{C}_{p}}\right) \tag{1}
\end{equation*}
$$

On the other hand, applying Remark 2.4 .2 with $R=o_{\mathbb{C}_{p}}$, we see that the natural map

$$
\begin{align*}
\operatorname{Hom}_{\mathrm{fgp} / o_{\mathbb{C}_{p}}}\left(\mathcal{G} \times_{o_{L}} o_{\mathbb{C}_{p}}\right. & \left., \widehat{\mathbb{G}}_{m} \times_{o_{L}} o_{\mathbb{C}_{p}}\right)  \tag{2}\\
& \rightarrow \operatorname{Hom}_{p-\operatorname{div} / o_{\mathbb{C}_{p}}}\left(\mathcal{G}(p) \times_{o_{L}} o_{\mathbb{C}_{p}}, \widehat{\mathbb{G}}_{m}(p) \times_{o_{L}} o_{\mathbb{C}_{p}}\right)
\end{align*}
$$

is a bijection. As a consequence, we see that $\operatorname{Hom}_{\mathrm{fgp}} / o_{\mathbb{C}_{p}}\left(\mathcal{G} \times{ }_{o_{L}} o_{\mathbb{C}_{p}}, \widehat{\mathbb{G}}_{m} \times{ }_{o_{L}} o_{\mathbb{C}_{p}}\right)$ is free of rank 1 as an $o_{L}$-module.

## Definition 2.6.1.

(1) We fix a generator $t_{o}^{\prime}$ for $T\left(\mathcal{G}(p)^{\vee}\right)$ as an $o_{L}$-module.
(2) We let $F_{t_{o}^{\prime}}$ be the generator for the $o_{L}$-module

$$
\operatorname{Hom}_{\mathrm{fgp} / o_{\mathbb{C}_{p}}}\left(\mathcal{G} \times_{o_{L}} o_{\mathbb{C}_{p}}, \widehat{\mathbb{G}}_{m} \times_{o_{L}} o_{\mathbb{C}_{p}}\right)
$$

which corresponds to $t_{o}^{\prime}$ along the isomorphism

$$
T\left(\mathcal{G}(p)^{\vee}\right) \stackrel{\cong}{\leftrightharpoons} \operatorname{Hom}_{\mathrm{fgp} / o_{\mathbb{C}_{p}}}\left(\mathcal{G} \times o_{o_{L}} o_{\mathbb{C}_{p}}, \widehat{\mathbb{G}}_{m} \times_{o_{L}} o_{\mathbb{C}_{p}}\right)
$$

obtained by combining (1) and (2).
(3) We let $\tau: G_{L} \rightarrow o_{L}^{\times}$be the character afforded by the free rank 1 $o_{L}$-module $T\left(\mathcal{G}(p)^{\vee}\right)$ :

$$
\sigma\left(t_{o}^{\prime}\right)=\tau(\sigma) t_{o}^{\prime} \quad \text { for all } \quad \sigma \in G_{L}
$$

The morphism of formal groups $F_{t_{o}^{\prime}}: \mathcal{G} \times{ }_{o_{L}} o_{\mathbb{C}_{p}} \rightarrow \widehat{\mathbb{G}}_{m} \times o_{o_{L}} o_{\mathbb{C}_{p}}$ is an element of

$$
F_{t_{o}^{\prime}}(Z) \in \mathcal{O}\left(\mathcal{G} \times_{o_{L}} o_{\mathbb{C}_{p}}\right)=o_{\mathbb{C}_{p}} \llbracket Z \rrbracket .
$$

Then $1+F_{t_{o}^{\prime}}(Z)$ is "grouplike" in the topological Hopf algebra $o_{\mathbb{C}_{p}} \llbracket Z \rrbracket$ : it satisfies the relation

$$
1+F_{t_{o}^{\prime}}\left(Z_{1} \oplus Z_{2}\right)=\left(1+F_{t_{o}^{\prime}}\left(Z_{1}\right)\right)\left(1+F_{t_{o}^{\prime}}\left(Z_{2}\right)\right)
$$

When we further base change the formal group $\mathcal{G} \times{ }_{o_{L}} o_{\mathbb{C}_{p}}$ to $\mathbb{C}_{p}$, it becomes isomorphic to the additive formal group. It follows from this that $\log F_{t_{o}^{\prime}}(Z)$ is necessarily "primitive" in the topological Hopf algebra $\mathbb{C}_{p} \llbracket Z \rrbracket$ : it satisfies the relation

$$
\begin{equation*}
\log \left(1+F_{t_{o}^{\prime}}\left(Z_{1} \oplus Z_{2}\right)\right)=\log \left(1+F_{t_{o}^{\prime}}\left(Z_{1}\right)\right)+\log \left(1+F_{t_{o}^{\prime}}\left(Z_{2}\right)\right) \tag{3}
\end{equation*}
$$

Since the logarithm $\log _{\mathrm{LT}}(Z)$ of the formal group $\mathcal{G}$ spans the space of primitive elements in $\mathbb{C}_{p} \llbracket Z \rrbracket$, it follows that there exists a unique element $\Omega \in \mathbb{C}_{p}$ such that

$$
1+F_{t_{o}^{\prime}}(Z)=\exp \left(\Omega \log _{\mathrm{LT}}(Z)\right)
$$

Definition 2.6.2. The element $\Omega$ is called the period of the dual $p$-divisible group $\mathcal{G}(p)^{\vee}$.

Let $I_{L} \subseteq G_{L}$ denote the inertia subgroup.
Lemma 2.6.3. If $L \neq \mathbb{Q}_{p}$, then the character $\tau: I_{L} \rightarrow o_{L}^{\times}$has an open image.
Proof. Let $\chi_{\pi}$ be the character describing the $G_{L}$-action on the Tate module $T$ of $\mathcal{G}$. By local class field theory we know that on $I_{L}, \operatorname{Norm}_{L / \mathbb{Q}_{p}} \circ \chi_{\pi}=\chi_{\text {cyc }}$, the cyclotomic character. From Definition 2.6.1(2), we have $\tau=\chi_{\pi}^{-1} \cdot \chi_{\text {cyc }}$. Hence $\tau: I_{L} \rightarrow o_{L}^{\times}$is the composition of the surjective map $\chi_{\pi}: I_{L} \rightarrow o_{L}^{\times}$and of the map given by $x \mapsto \prod_{\sigma: L \rightarrow \overline{\mathbb{Q}}_{p}, \sigma \neq \mathrm{Id}} \sigma(x)$.

On the Lie algebra $L$ of $o_{L}^{\times}$, the derivative of the above map is given by $U=\operatorname{Tr}_{L / \mathbb{Q}_{p}}$ - Id. We prove that $U: L \rightarrow L$ is injective, hence surjective, which implies the lemma. If $U(x)=0$, then $x=(U+\mathrm{Id}) x=\operatorname{Tr}_{L / \mathbb{Q}_{p}}(x) \in \mathbb{Q}_{p}$ and hence $U(x)=\left(\left[L: \mathbb{Q}_{p}\right]-1\right) x$ so that $x=0$.

For future use, we record here the more precise result (pointed out to us by B. Xie) which gives a sufficient criterion for $\tau$ to be surjective.

Lemma 2.6.4. If $d-1$ and $(p-1) p$ are coprime, then $\tau: I_{L} \rightarrow o_{L}^{\times}$is surjective.
Proof. Since $\tau=\chi_{\pi}^{-1} \cdot \chi_{\text {cyc }}$ and $\chi_{\text {cyc }}=\operatorname{Norm}_{L / \mathbb{Q}_{p}} \circ \chi_{\pi}$, we have

$$
\tau(g)=\chi_{\pi}(g)^{-1} \operatorname{Norm}_{L / \mathbb{Q}_{p}}\left(\chi_{\pi}(g)\right) \quad \text { for any } g \in I_{L}
$$

Note also that the restriction to $I_{L}$ of the totally ramified surjective character $\chi_{\pi} \rightarrow o_{L}^{\times}$is still surjective. Let now $u \in o_{L}^{\times}$be any fixed element.

We first show that there is an $a \in \mathbb{Z}_{p}^{\times}$such that $a^{d-1}=\operatorname{Norm}_{L / \mathbb{Q}_{p}}(u)$. Let $v:=\operatorname{Norm}_{L / \mathbb{Q}_{p}}(u)$ and let $\bar{v}$ denote its image in $\mathbb{F}_{p}^{\times}$. By our assumption the
polynomial $Z^{d-1}-\bar{v}$ is separable over $\mathbb{F}_{p}$ and has a root in $\mathbb{F}_{p}^{\times}$. Hence Hensel's Lemma implies that the polynomial $Z^{d-1}-v$ has a root $a \in \mathbb{Z}_{p}^{\times}$.

Choosing now a $g \in I_{L}$ such that $\chi_{\pi}(g)=a u^{-1}$ we deduce that

$$
\tau(g)=\left(a u^{-1}\right)^{-1} \operatorname{Norm}_{L / \mathbb{Q}_{p}}\left(a u^{-1}\right)=u a^{-1} a^{d} \operatorname{Norm}_{L / \mathbb{Q}_{p}}\left(u^{-1}\right)=u
$$

2.7. The Amice-Katz transform. With the period $\Omega \in \mathbb{C}_{p}$ in hand, we now recall some constructions from $p$-adic Fourier Theory [28]. For each $a \in o_{L}$, define

$$
\Delta_{a}:=1+F_{a t_{o}^{\prime}}(Z)=\exp \left(a \Omega \log _{\mathrm{LT}}(Z)\right) \in \mathbb{C}_{p} \llbracket Z \rrbracket^{\times}
$$

The map $\left(o_{L},+\right) \rightarrow\left(\mathbb{C}_{p} \llbracket Z \rrbracket^{\times}, \times\right)$which sends $a \in o_{L}$ to $\Delta_{a}$ is a group homomorphism. The fundamental property of these power series is that their coefficients all lie in $o_{\mathbb{C}_{p}}$ :

$$
\Delta_{a} \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{\times} \quad \text { for all } \quad a \in o_{L} .
$$

This follows from the fact that for each $a \in o_{L}, F_{a t_{o}^{\prime}}: \mathcal{G} \times o_{o_{L}} o_{\mathbb{C}_{p}} \rightarrow \widehat{\mathbb{G}}_{m} \times_{o_{L}} o_{\mathbb{C}_{p}}$ is a homomorphism of formal groups defined over $o_{\mathbb{C}_{p}}$; see also [28, Lemma 4.2(5)].

## Definition 2.7.1.

(1) Let $L_{\infty}$ be the closure in $\mathbb{C}_{p}$ of the subfield $L(\Omega)$ of $\mathbb{C}_{p}$ generated by $L$ and $\Omega$.
(2) Let $L_{\tau}:=L_{\infty} \cap \bar{L}$.
(3) Let $o_{\infty}:=L_{\infty} \cap o_{\mathbb{C}_{p}}$.
(4) Let $o_{\tau}:=L_{\tau} \cap o_{\mathbb{C}_{p}}$.

Lemma 2.7.2. We have $L_{\infty}=\mathbb{C}_{p}^{\mathrm{ker} \tau}$ and $o_{\infty}=o_{\mathbb{C}_{p}}^{\mathrm{ker} \tau}$.
Proof. From the relation appearing in Definition 2.6.1(3), we deduce

$$
\sigma(\Omega)=\tau(\sigma) \Omega \quad \text { for all } \quad \sigma \in G_{L}
$$

This immediately implies that $L_{\infty} \subseteq \mathbb{C}_{p}^{\mathrm{ker} \tau}$. Let $H:=\operatorname{Gal}\left(\bar{L} / L_{\tau}\right)$, a closed subgroup of $G_{L}$, and let $g \in H$. Then $g$ extends to a unique continuous $L_{\tau^{-}}$ linear automorphism $g$ of $\mathbb{C}_{p}$. Now $L_{\infty}$ is the closure of $L_{\tau}$ in $\mathbb{C}_{p}$, so $g$ fixes $\Omega \in L_{\infty}$. Hence $\tau(g)=1$ by the above relation. Hence $H \leq \operatorname{ker} \tau$ which implies that $\mathbb{C}_{p}^{\mathrm{ker} \tau} \leq \mathbb{C}_{p}^{H}$. But $\bar{L}^{H}$ is dense in $\mathbb{C}_{p}^{H}$ by the Ax-Sen-Tate theorem, $[9$, Proposition 2.1.2], and $\bar{L}^{H}=L_{\tau}$ by infinite Galois theory. Hence $L_{\tau}$ is dense in $\mathbb{C}_{p}^{H}$, so $\mathbb{C}_{p}^{H}$ is contained in the closure of $L_{\tau}$ in $\mathbb{C}_{p}$, namely $L_{\infty}$. Hence $\mathbb{C}_{p}^{\mathrm{ker} \tau} \leq L_{\infty}$.

The second statement follows from the first by intersecting $L_{\infty}=\mathbb{C}_{p}^{\mathrm{ker} \tau}$ with $o_{\mathbb{C}_{p}}$.

It is clear from the definition of $\Delta_{a}$ that in fact $\Delta_{a} \in o_{\infty} \llbracket Z \rrbracket^{\times}$for all $a \in o_{L}$.

Definition 2.7.3. We write $o_{L} \llbracket o_{L} \rrbracket$ for the completed group ring of the abelian group $o_{L}$ with coefficients in $o_{L}$. The Amice-Katz transform is the unique extension to a continuous $o_{L}$-algebra homomorphism

$$
\mu: o_{L} \llbracket o_{L} \rrbracket \rightarrow \mathcal{O}\left(\mathcal{G} \times_{o_{L}} o_{\infty}\right)=o_{\infty} \llbracket Z \rrbracket
$$

of the group homomorphism $o_{L} \rightarrow o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{\times}$which sends $a \in o_{L}$ to $\Delta_{a} \in$ $o_{\infty} \llbracket Z \rrbracket^{\times}$.
2.8. The Schneider-Teitelbaum uniformisation. At this point, rigid analytic geometry enters the picture. Let $\mathbf{B}$ be the rigid $L_{\infty}$-analytic open disc of radius one, with local coordinate $Z$. By definition, $\mathbf{B}$ is the colimit of the rigid $L_{\infty}$-analytic closed discs $\mathbf{B}(r)$ of radius $r<1$, as $r \in\left|L_{\infty}^{\times}\right|$approaches 1 from below:

$$
\mathbf{B}=\operatorname{colim}_{r<1} \mathbf{B}(r), \quad \mathbf{B}(r)=\operatorname{Sp} L_{\infty}\langle Z / \dot{r}\rangle
$$

where $\dot{r}$ is any choice of an element of $L_{\infty}^{\times}$such that $|\dot{r}|=r$. Choosing, for convenience, any strictly increasing sequence $r_{1}<r_{2}<r_{3}<\cdots$ of real numbers in $\left|L_{\infty}\right| \cap(0,1)$ approaching 1 from below, we have a descending chain of $L_{\infty}$-algebras, each one containing $o_{\infty} \llbracket Z \rrbracket$ :

$$
\begin{aligned}
L_{\infty}\left\langle Z / \dot{r}_{1}\right\rangle \supsetneq L_{\infty}\left\langle Z / \dot{r}_{2}\right\rangle \supsetneq L_{\infty}\left\langle Z / \dot{r}_{3}\right\rangle \supsetneq \cdots \supsetneq \bigcap_{n=1}^{\infty} & L_{\infty}\left\langle Z / \dot{r}_{n}\right\rangle \\
& =\mathcal{O}(\mathbf{B}) \supseteq o_{\infty} \llbracket Z \rrbracket \otimes_{o_{L}} L .
\end{aligned}
$$

With this notation in place, it follows from one of Schneider-Teitelbaum's main results, $\left[28\right.$, Theorem 3.6], that the $o_{L}$-algebra homomorphism $\mu: o_{L} \llbracket o_{L} \rrbracket \rightarrow$ $o_{\infty} \llbracket Z \rrbracket$ extends to a continuous isomorphism of $L$-Fréchet algebras

$$
\mu_{\mathrm{rig}}: D^{L-\mathrm{an}}\left(o_{L}, L_{\infty}\right) \stackrel{\cong}{\longrightarrow} \mathcal{O}(\mathbf{B})
$$

which makes the following diagram commutative:

The vertical arrow on the left is the natural restriction map $o_{L} \llbracket o_{L} \rrbracket \otimes_{o_{L}} L$ into $D^{L-a n}\left(o_{L}, L\right)$, witnessing the fact that every locally $L$-analytic function on $o_{L}$ is continuous, and hence that every continuous distribution on $o_{L}$ restricts to a locally $L$-analytic distribution on $o_{L}$; see [29] for more details. The vertical arrow on the right is the inclusion $o_{\infty} \llbracket Z \rrbracket \otimes_{o_{L}} L \subset \mathcal{O}(\mathbf{B})$ from the above discussion. Combining the isomorphism $\mu_{\text {rig }}$ with the Fourier transform $\mathcal{F}: D^{L-\mathrm{an}}\left(o_{L}, L_{\infty}\right) \rightarrow \mathcal{O}\left(\mathfrak{X} \times_{L} L_{\infty}\right)$, we obtain an isomorphism of $L_{\infty}$-Fréchet algebras

$$
\mu_{\mathrm{rig}} \circ \mathcal{F}^{-1}: \mathcal{O}\left(\mathfrak{X} \times_{L} L_{\infty}\right) \xrightarrow{\cong} \mathcal{O}(\mathbf{B})
$$

Since $\mathfrak{X} \times_{L} L_{\infty}$ and $\mathbf{B}$ are both Stein rigid analytic varieties over $L_{\infty}$, this isomorphism determines, and is completely determined by, an isomorphism

$$
\kappa:=\operatorname{Sp}\left(\mu_{\text {rig }} \circ \mathcal{F}^{-1}\right): \mathbf{B} \stackrel{\cong}{\Longrightarrow} \mathfrak{X} \times_{L} L_{\infty} .
$$

This is a version of [28, Theorem 3.6]: the base-change of the character variety $\mathfrak{X}$ to $L_{\infty}$ is isomorphic to the rigid $L_{\infty}$-analytic open disc of radius one, so $\kappa$ can be viewed as giving a uniformisation of $\mathfrak{X} \times_{L} L_{\infty}$ by B. Schneider and Teitelbaum also show that the morphism $\kappa$ is given on $\mathbb{C}_{p}$-points by the following rule: for each $z \in \mathbf{B}\left(\mathbb{C}_{p}\right)$ we can evaluate the power series $\Delta_{a} \in$ $o_{\infty} \llbracket Z \rrbracket$ at $Z=z$ to obtain an element $\Delta_{a}(z) \in o_{\mathbb{C}_{p}}^{\times}$, and the locally $L$-analytic character $\kappa(z): o_{L} \rightarrow \mathbb{C}_{p}$ is given by

$$
\kappa(z)(a)=\Delta_{a}(z) \quad \text { for all } \quad a \in o_{L} .
$$

2.9. $\Lambda_{L}(\mathfrak{X})$ and the twisted $G_{L}$-action on $\mathbb{C}_{p} \llbracket Z \rrbracket$. It is natural to enquire, in the light of the Schneider-Teitelbaum isomorphism

$$
\kappa: \mathbf{B} \xrightarrow{\cong} \mathfrak{X} \times_{L} L_{\infty}
$$

how far the character variety $\mathfrak{X}$ is itself from being isomorphic to an open rigid $L$-analytic unit disc. For general reasons, $\mathfrak{X} \times{ }_{L} L_{\infty}$ carries a natural action of the Galois group $G_{L}$, acting on the second factor, giving an isomorphism of $L$-Fréchet algebras

$$
\mathcal{O}(\mathfrak{X}) \cong \mathcal{O}\left(\mathfrak{X} \times_{L} L_{\infty}\right)^{G_{L}}
$$

Definition 2.9.1. The twisted $G_{L}$-action on $\mathcal{O}(\mathbf{B})$ is given as follows:

$$
\sigma * F(Z):=\left({ }^{\sigma} F\right)\left(\left[\tau(\sigma)^{-1}\right](Z)\right) \quad \text { for all } \quad F(Z) \in \mathcal{O}(\mathbf{B}), \sigma \in G_{L}
$$

Here $F \mapsto{ }^{\sigma} F$ is the "coefficient-wise" $G_{L}$-action on $\mathbb{C}_{p} \llbracket Z \rrbracket \supset \mathcal{O}(\mathbf{B})$, given explicitly by ${ }^{\sigma}\left(\sum_{n=0}^{\infty} a_{n} Z^{n}\right)=\sum_{n=0}^{\infty} \sigma\left(a_{n}\right) Z^{n}$ for all $\sigma \in G_{L}$.

Schneider and Teitelbaum showed that this twisted $G_{L}$-action on $\mathcal{O}(\mathbf{B})$ in fact comes from the following twisted $G_{L}$-action on the set of $\mathbb{C}_{p}$-points $\mathbf{B}\left(\mathbb{C}_{p}\right)$ :

$$
\sigma * z=\kappa^{-1}(\sigma \circ \kappa(z)) \quad \text { for all } \quad z \in \mathbf{B}\left(\mathbb{C}_{p}\right), \sigma \in G_{L}
$$

From the proof of [28, Corollary 3.8], we can also deduce the following
Proposition 2.9.2. The algebra isomorphism

$$
\kappa^{*}=\mu_{\text {rig }} \circ \mathcal{F}^{-1}: \mathcal{O}\left(\mathfrak{X} \times_{L} L_{\infty}\right) \xrightarrow{\cong} \mathcal{O}(\mathbf{B})
$$

is equivariant with respect to the natural $G_{L}$-action on the source, and the twisted $G_{L}$-action on the target.

Corollary 2.9.3. The map $\mu_{\text {rig }}$ restricts to give an isomorphism of o $o_{L}$-algebras

$$
\left(\mu_{\text {rig }} \circ \mathcal{F}^{-1}\right)^{\circ}: \mathcal{O}^{\circ}(\mathfrak{X}) \xrightarrow{\cong} o_{\infty} \llbracket Z \rrbracket^{G_{L}, *} .
$$

Proof. Applying the functor $\mathcal{O}^{\circ}$ to the isomorphism of rigid $L_{\infty}$-analytic varieties $\kappa: \mathbf{B} \rightarrow \mathfrak{X} \times{ }_{L} L_{\infty}$, we see that $\mu_{\text {rig }} \circ \mathcal{F}^{-1}$ restricts to an $o_{\infty}$-algebra isomorphism

$$
\mathcal{O}\left(\mathfrak{X} \times_{L} L_{\infty}\right)^{\circ} \xrightarrow{\cong} \mathcal{O}(\mathbf{B})^{\circ} .
$$

It is well known that $\mathcal{O}(\mathbf{B})^{\circ}=o_{\infty} \llbracket Z \rrbracket$ and that $\Lambda_{L}(\mathfrak{X})=\mathcal{O}(\mathfrak{X})^{\circ}=\left(\mathcal{O}\left(\mathfrak{X} \times_{L}\right.\right.$ $\left.\left.L_{\infty}\right)^{\circ}\right)^{G_{L}}$. The result follows by passing to $G_{L}$-invariants and applying Proposition 2.9.2.

Consequently, the image of the Amice-Katz transform $\mu: o_{L} \llbracket o_{L} \rrbracket \rightarrow o_{\infty} \llbracket Z \rrbracket$ lands in the subring of twisted $G_{L}$-invariants. One of our main goals in this paper is to study the following
Question 2.9.4. Is the Amice-Katz transform $\mu: o_{L} \llbracket o_{L} \rrbracket \rightarrow o_{\infty} \llbracket Z \rrbracket^{G_{L}, *}$ an isomorphism?
2.10. Some properties of $\Lambda_{L}(\mathfrak{X})$. In this section, we identify (through the LT-isomorphism) the ring $\Lambda_{L}(\mathfrak{X})=\mathcal{O}(\mathfrak{X})^{\circ}$ with the ring $o_{\infty} \llbracket Z \rrbracket^{G_{L}, *}$. From [5] we know that $\Lambda_{L}(\mathfrak{X})$ is an integral domain and that the norm $\left\|\left\|_{\mathfrak{X}}=\right\|\right\|_{1}$ on $\Lambda_{L}(\mathfrak{X})$ is multiplicative. Let $k_{K}$ denote the residue field of $K$.
Lemma 2.10.1. If $L \neq \mathbb{Q}_{p}$ and if $K$ is a finite extension of $L$, then $\bar{k} \llbracket Z \rrbracket^{G_{K}, *}=$ $k_{K}$.

Proof. If $g \in I_{K}$, then $g$ acts trivially on $\bar{k}$, so that the $G_{L, *}$ action of $g \in I_{K}$ on $\bar{k} \llbracket Z \rrbracket$ is given by $g: \sum_{n \geq 0} a_{n} Z^{n} \mapsto \sum_{n \geq 0} a_{n}\left(\left[\tau(g)^{-1}\right] Z\right)^{n}$. The character $\tau: I_{K} \rightarrow o_{L}^{\times}$has an open image by Lemma 2.6.3. This image therefore contains $\chi_{\pi}\left(I_{M}\right)$ where $M \subset L_{\infty}$ is some finite extension of $L$, and $\bar{k} \llbracket Z \rrbracket^{I_{K}, *}=\bar{k} \llbracket Z \rrbracket^{I_{M}}$ where $I_{M}$ acts on $\bar{k} \llbracket Z \rrbracket$ via $g: \sum_{n \geq 0} a_{n} Z^{n} \mapsto \sum_{n \geq 0} a_{n}\left(\left[\chi_{\pi}(g)\right] Z\right)^{n}$. We know from the theory of the field of norms that $\bar{k} \llbracket Z \rrbracket$ with that action of $I_{M}$ embeds into $\tilde{\mathbf{E}}^{+} \simeq \lim _{(-)^{q}} o_{\mathbb{C}_{p}}$ in an $I_{M}$-equivariant way. Let $P:=\mathbb{C}_{p}^{I_{M}}$. We have $\left(\tilde{\mathbf{E}}^{+}\right)^{I_{M}} \simeq \lim _{(-)^{q}} o_{P}=\bar{k}$ since $P / \mathbb{Q}_{p}$ is finitely ramified. Hence $\bar{k} \llbracket Z \rrbracket^{I_{M}}=\bar{k}$ and $\bar{k} \llbracket Z \rrbracket^{I_{K}, *}=\bar{k}$. The Lemma then follows from the fact that on $\bar{k}$, the twisted $G_{L}$-action coincides with the usual $G_{L}$-action, so that $\bar{k}^{G_{K}, *}=k_{K}$.

Let $\chi_{\text {triv }}$ denote the character $o_{L} \rightarrow \mathbb{C}_{p}^{\times}$given by $\chi_{\text {triv }}(a)=1$ for all $a \in o_{L}$. Note that $\chi_{\text {triv }}=\kappa(0)$. We have a surjective map $\Lambda_{L}(\mathfrak{X}) \rightarrow k$ given by $f \mapsto f\left(\chi_{\text {triv }}\right) \bmod \mathfrak{m}_{L}$. Its kernel $\mathfrak{m}(\mathfrak{X}):=\left\{f \in \Lambda_{L}(\mathfrak{X}): f\left(\chi_{\text {triv }}\right) \in \mathfrak{m}_{L}\right\}$ is a maximal ideal of $\Lambda_{L}(\mathfrak{X})$, with residue field $k$. Lemma 2.10.1 above implies that $\mathfrak{m}(\mathfrak{X})=\mathfrak{m}_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{G_{L}, *}$
Lemma 2.10.2. The ring $\Lambda_{L}(\mathfrak{X})$ is a local ring.
Proof. We have to show that $\mathfrak{m}(\mathfrak{X})$ is the unique maximal ideal, i.e., that $f$ is a unit in $\Lambda_{L}(\mathfrak{X})$ if and only if $f\left(\chi_{\text {triv }}\right) \in o_{L}^{\times}$. The direct implication is obvious. We therefore assume that $f\left(\chi_{\text {triv }}\right) \in o_{L}^{\times}$. The image $F(Z) \in o_{\mathbf{C}_{p}} \llbracket Z \rrbracket$ of $f$ under the LT-isomorphism then satisfies $F(0) \in o_{L}^{\times}$and hence is a unit in $o_{\mathbf{C}_{p}} \llbracket Z \rrbracket$. We deduce that $f$ is a unit in $\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$. Since the twisted $G_{L}$-action must fix
with $f$ also its inverse we obtain that $f$ is a unit in $\mathcal{O}_{L}(\mathfrak{X})$ and hence in $\mathcal{O}_{L}^{b}(\mathfrak{X})$ by [5] Cor. 1.24. The multiplicativity of the norm $\left\|\|_{\mathfrak{X}}\right.$ finally implies that $1=\|f\|_{\mathfrak{X}}=\left\|f^{-1}\right\|_{\mathfrak{X}}$.

The $o_{L}$-algebra $\Lambda_{L}(\mathfrak{X})$ carries two natural topologies. One is the $p$-adic topology which is induced by the norm $\left\|\|_{\mathfrak{X}}\right.$. The other is the topology induced by the Fréchet topology of $\mathcal{O}_{L}(\mathfrak{X})$. We will call the latter the weak topology on $\Lambda_{L}(\mathfrak{X})$.

Remark 2.10.3. The weak topology on $\Lambda_{L}(\mathfrak{X})$ is coarser than the $p$-adic topology.
Proof. Let $\mathfrak{X}=\bigcup_{n \geq 1} \mathfrak{X}_{n}$ be a Stein covering by affinoid subdomains $\mathfrak{X}_{n}$ (cf. [5] §1.3). The Fréchet topology of $\mathcal{O}_{L}(\mathfrak{X})$ is the projective limit of the Banach topologies on the affinoid algebras $\mathcal{O}_{L}\left(\mathfrak{X}_{n}\right)$. Since $\mathfrak{X}$ is reduced these Banach topologies are defined by the respective supremum norm (cf. [7, Thm. 6.2.4/1] ). Therefore the Banach topology on $\mathcal{O}_{L}\left(\mathfrak{X}_{n}\right)$ induces on its unit ball with respect to the supremum norm the $p$-adic topology. It follows that the natural maps $\Lambda_{L}(\mathfrak{X}) \rightarrow \mathcal{O}_{L}\left(\mathfrak{X}_{n}\right)$ are continuous for the $p$-adic topology on the source and the Banach topology on the target. Therefore the inclusion $\Lambda_{L}(\mathfrak{X}) \subseteq \mathcal{O}_{L}(\mathfrak{X})$ is continuous for the $p$-adic topology on the source and the Fréchet topology on the target.

Lemma 2.10.4. The $o_{L}$-module $\Lambda_{L}(\mathfrak{X})$ is p-adically separated and complete.
Proof. We show that, for any reduced rigid analytic variety $\mathfrak{Y}$ over $L$, the ring $\mathcal{O}_{L}^{\leq 1}(\mathfrak{Y})$ of holomorphic functions bounded by 1 is $p$-adically separated and complete. Let $\mathfrak{Y}=\bigcup_{i \in I} \mathfrak{Y}_{i}$ be an admissible covering by affinoid subdomains. Since $\mathfrak{Y}$ is assumed to be reduced, the supremum seminorm on each $\mathcal{O}_{L}\left(\mathfrak{Y}_{i}\right)$ is a norm and defines its affinoid Banach topology (cf. [5, §1.3] ). Hence $\left\|\|_{\mathfrak{Y}}\right.$ is a norm on $\mathcal{O}_{L}^{b}(\mathfrak{Y})$ and defines the $p$-adic topology on $\mathcal{O}_{L}^{\leq 1}(\mathfrak{Y})$. In particular, the $p$-adic topology on $\mathcal{O}_{L}^{\leq 1}(\mathfrak{Y})$ is separated. Now let $\left(f_{n}\right)_{n}$ be a Cauchy sequence for $\left\|\|_{\mathfrak{Y}}\right.$ in $\mathcal{O}_{L}^{\leq 1}(\mathfrak{Y})$. It restricts to a Cauchy sequence in $\mathcal{O}_{L}^{\leq 1}\left(\mathfrak{Y}_{i}\right)$ for each $i \in I$ which converges to a function $g_{i} \in \mathcal{O}_{L}^{\leq 1}\left(\mathfrak{Y}_{i}\right)$. Obviously the $g_{i}$ glue to a function $g \in \mathcal{O}_{L}^{\leq 1}(\mathfrak{Y})$. We have to show that the sequence $\left(f_{n}\right)_{n}$ converges to $g$ with respect to $\left\|\|_{\mathfrak{Y}}\right.$. Let $\epsilon>0$ be arbitrary. First we find an integer $N>0$ such that $\left\|f_{m}-f_{n}\right\|_{\mathfrak{Y}}<\epsilon$ for all $m, n>N$. Secondly, for any $i \in I$, we have $\left\|g-f_{m}\right\|_{\mathfrak{Y}_{i}}<\epsilon$ for all sufficiently large (depending on $i$ ) $m$. It follows that $\left\|g-f_{n}\right\|_{\mathfrak{Y}_{i}} \leq \max \left(\left\|g-f_{m}\right\|_{\mathfrak{Y}_{i}},\left\|f_{m}-f_{n}\right\|_{\mathfrak{Y}_{i}}\right) \leq \max \left(\left\|g-f_{m}\right\|_{\mathfrak{Y}_{i}},\left\|f_{m}-f_{n}\right\|_{\mathfrak{Y}}\right)<$ $\epsilon$ for any $n>N$ and any $i \in I$. Hence $\left\|g-f_{n}\right\|_{\mathfrak{Y}} \leq \epsilon$ for any $n>N$.

Proposition 2.10.5. The $o_{L}$-module $\Lambda_{L}(\mathfrak{X})$ is compact in the weak topology.
Proof. According to [13, Prop. 6.4.5] the space $\mathfrak{X}$ is strictly quasi-Stein. This means that a Stein covering $\mathfrak{X}=\bigcup_{n \geq 1} \mathfrak{X}_{n}$ can be chosen such that the inclusion maps $\mathfrak{X}_{n} \subseteq \mathfrak{X}_{n+1}$ are relatively compact. By loc. cit. Prop. 2.1.16 this implies that the restriction maps $\mathcal{O}_{L}\left(\mathfrak{X}_{n+1}\right) \rightarrow \mathcal{O}_{L}\left(\mathfrak{X}_{n}\right)$, which we simply view as inclusions, are compact maps between Banach spaces. Working over a locally
compact field we deduce (cf. [27, Remark 16.3] and [24, Cor. 6.1.14] ) that the closure $C_{n}$ of $\mathcal{O}_{L}^{\leq 1}\left(\mathfrak{X}_{n+1}\right)$ in $\mathcal{O}_{L}\left(\mathfrak{X}_{n}\right)$ is compact. We, of course, have $\Lambda_{L}(\mathfrak{X}) \subseteq$ $\mathcal{O}_{L}^{\leq 1}\left(\mathfrak{X}_{n+1}\right) \subseteq C_{n}$. Therefore, if $\mathcal{L}_{n} \subseteq \mathcal{O}_{L}\left(\mathfrak{X}_{n}\right)$ is any open lattice, then the $o_{L^{-}}$ modules $\Lambda_{L}(\mathfrak{X}) / \Lambda_{L}(\mathfrak{X}) \cap \mathcal{L}_{n} \subseteq C_{n} / C_{n} \cap \mathcal{L}_{n}$ are finite. It is straightforward to see that then $\Lambda_{L}(\mathfrak{X}) / \Lambda_{L}(\mathfrak{X}) \cap \mathcal{L}$ must be finite for any open lattice $\mathcal{L} \subseteq \mathcal{O}_{L}(\mathfrak{X})$. On the other hand $\Lambda_{L}(\mathfrak{X})$ is weakly closed in $\mathcal{O}_{L}(\mathfrak{X})$ and hence is weakly complete. It follows [27, Cor. 7.6] that $\Lambda_{L}(\mathfrak{X})$ with its weak topology is the projective limit of the finite groups $\Lambda_{L}(\mathfrak{X}) / \Lambda_{L}(\mathfrak{X}) \cap \mathcal{L}$ and hence is compact.
Lemma 2.10.6.
(1) Any open neighbourhood of zero for the weak topology on $\Lambda_{L}(\mathfrak{X})$ contains a power of the maximal ideal $\mathfrak{m}(\mathfrak{X})$.
(2) If the ideal $\mathfrak{m}(\mathfrak{X})$ is finitely generated then the weak topology on $\Lambda_{L}(\mathfrak{X})$ coincides with the $\mathfrak{m}(\mathfrak{X})$-adic topology.
Proof. We have $\mathfrak{m}(\mathfrak{X})=\pi_{L} \Lambda_{L}(\mathfrak{X})+\mathfrak{n}$, where $\mathfrak{n}$ denotes the ideal of all functions in $\Lambda_{L}(\mathfrak{X})$ which vanish in $\chi_{\text {triv }}$. We consider the divisor $\Delta$ on $\mathfrak{X}$ which maps $\chi_{\text {triv }}$ to 1 and all other points to zero. For any integer $m \geq 1$ we have the ideal $I_{m \Delta} \subseteq \mathcal{O}_{L}(\mathfrak{X})$ corresponding to the divisor $m \Delta$. As a consequence of $[5$, Prop. 1.4] these ideals are closed in $\mathcal{O}_{L}(\mathfrak{X})$ and satisfy $\bigcap_{m} I_{m}=\{0\}$. Hence the ideals $I_{m} \cap \Lambda_{L}(\mathfrak{X})$ are closed in $\Lambda_{L}(\mathfrak{X})$ with zero intersection. Let now $U \subseteq \Lambda_{L}(\mathfrak{X})$ be any fixed open neighbourhood of zero for the weak topology. Suppose that $I_{m} \cap \Lambda_{L}(\mathfrak{X}) \nsubseteq U$ for any $m \geq 1$. We then may pick, for any $m \geq 1$, a function $f_{m} \in\left(I_{m} \cap \Lambda_{L}(\mathfrak{X})\right) \backslash U$. According to Proposition 2.10.5 the weak topology on $\Lambda_{L}(\mathfrak{X})$ is compact. Hence the sequence $\left(f_{m}\right)_{m}$ has a convergent subsequence with a limit $f \in \Lambda_{L}(\mathfrak{X})$. On the one hand we have $f_{n} \in I_{m} \cap \Lambda_{L}(\mathfrak{X})$ for any $n \geq m$. Since $I_{m} \cap \Lambda_{L}(\mathfrak{X})$ is closed it follows that $f \in I_{m} \cap \Lambda_{L}(\mathfrak{X})$ for any $m \geq 1$. Therefore $f=0$. But on the other hand all the $f_{m}$ and hence $f$ lie in the closed complement of the open subset $U$. This is a contradiction. We conclude that $\mathfrak{n}^{m} \subseteq I_{m} \cap \Lambda_{L}(\mathfrak{X}) \subseteq U$ for any sufficiently large $m$. As a consequence of Remark 2.10 .3 we also have $\pi_{L}^{m} \Lambda_{L}(\mathfrak{X}) \subseteq U$ for any sufficiently large $m$. Hence $\mathfrak{m}(\mathfrak{X})^{2 m} \subseteq \pi_{L}^{m} \Lambda_{L}(\mathfrak{X})+\mathfrak{n}^{m} \subseteq U$ for large $m$. This proves (1).

We have to show that the ideals $\mathfrak{m}(\mathfrak{X})^{m}$ are open for the weak topology. Under our assumption all ideals $\mathfrak{m}(\mathfrak{X})^{m}$, for $m \geq 1$, are finitely generated. Hence all $\mathfrak{m}(\mathfrak{X})^{m+1} / \mathfrak{m}(\mathfrak{X})^{m}$ are finite dimensional $k$-vector spaces. We see that each quotient $\Lambda_{L}(\mathfrak{X}) / \mathfrak{m}(\mathfrak{X})^{m}$, for $m \geq 1$, is a finite $o_{L}$-module. Hence it suffices to show that the ideal $\mathfrak{m}(\mathfrak{X})^{m}$ is closed for the weak topology. Let $f_{1}, \ldots, f_{r}$ be generators of $\mathfrak{m}(\mathfrak{X})^{m}$. Then $\mathfrak{m}(\mathfrak{X})^{m}$ is the image of the map $\Lambda_{L}(\mathfrak{X})^{r} \rightarrow \Lambda_{L}(\mathfrak{X})$ sending $\left(h_{1}, \ldots, h_{r}\right)$ to $\sum_{i} h_{i} f_{i}$, which is a continuous map between compact spaces by Proposition 2.10.5. This proves (2).

Remark 2.10.7. Any $f \in \mathfrak{m}(\mathfrak{X})$ satisfies $\|f\|_{\mathfrak{X}_{n}}<1$ for all $n$.
Proof. If $\|f\|_{\mathfrak{X}_{n}}=1$ then the maximum modulus principle for the affinoid $\mathfrak{X}_{n}$ implies that there is a point $z \in \mathfrak{X}_{n}$ such that $|f(z)|=1$. By considering $f$ as an element of $o_{\mathbb{C}_{p}} \llbracket T \rrbracket$, we see that $f(0)$ is a unit so that $f$ is not in $\mathfrak{m}(\mathfrak{X})$.

Next we consider the injective map

$$
\Lambda\left(o_{L}\right)=o_{L} \llbracket o_{L} \rrbracket \longrightarrow \Lambda_{L}(\mathfrak{X})
$$

which we treat as an inclusion. More explicitly, let $a_{1}, \ldots a_{d}$ be a basis of $o_{L}$ as a $\mathbb{Z}_{p}$-module. Then the image of the above map is the ring of formal power series $o_{L} \llbracket \delta_{a_{1}}-\delta_{0}, \ldots, \delta_{a_{d}}-\delta_{0} \rrbracket$ inside $\Lambda_{L}(\mathfrak{X})$. We immediately conclude from Lemma 2.10.1 that

$$
\mathfrak{m}(\mathfrak{X}) \cap o_{L} \llbracket o_{L} \rrbracket=\left\langle\pi_{L}, \delta_{a_{1}}-\delta_{0}, \ldots, \delta_{a_{d}}-\delta_{0}\right\rangle \subseteq o_{L} \llbracket o_{L} \rrbracket .
$$

Lemma 2.10.8. We have $\mathcal{O}_{L}^{<1}(\mathfrak{X}) \cap o_{L} \llbracket o_{L} \rrbracket=\pi_{L} o_{L} \llbracket o_{L} \rrbracket$.
Proof. We have $\pi_{L} o_{L} \llbracket o_{L} \rrbracket \subseteq P:=\mathcal{O}_{L}^{<1}(\mathfrak{X}) \cap o_{L} \llbracket o_{L} \rrbracket$. It follows that $\bar{P}:=$ $P / \pi_{L} o_{L} \llbracket o_{L} \rrbracket$ is a "canonical" prime ideal in the formal power series ring $k \llbracket o_{L} \rrbracket$ : in particular, it is invariant for the $o_{L}^{\times}$action on the mod- $p$ Iwasawa algebra $k \llbracket o_{L} \rrbracket$. Suppose for a contradiction that $\bar{P}$ is the (unique) maximal ideal of $k \llbracket o_{L} \rrbracket$. Then $P$ would contain $\delta_{a_{1}}-\delta_{0}$ and we would have $\left\|\delta_{a_{1}}-\delta_{0}\right\|_{\mathfrak{X}}<1$. For each $n \geq 0$, let $\zeta_{p^{n}} \in o_{\mathbb{C}_{p}}$ denote a primitive $p^{n}$-root of unity, and let $\chi_{n}: o_{L} \rightarrow \mathbb{C}_{p}^{\times}$be the unique torsion (hence locally $L$-analytic) character of $o_{L}$ that sends $a_{1}$ to $\zeta_{p^{n}}$ and $a_{i}$ to 1 for all $i>1$. Then $\chi_{n} \in \mathfrak{X}\left(\mathbb{C}_{p}\right)$, and $\left|\left(\delta_{a_{1}}-\delta_{0}\right)\left(\chi_{n}\right)\right| \leq\left\|\delta_{a_{1}}-\delta_{0}\right\|_{\mathfrak{X}}<1$ for all $n \geq 0$. However, $\left|\left(\delta_{a_{1}}-\delta_{0}\right)\left(\chi_{n}\right)\right|=$ $\left|\zeta_{p^{n}}-1\right|=|p|^{\frac{p^{n-1}(p-1)}{}}$ tends to 1 from below, which is a contradiction. Hence $\bar{P}$ is not the maximal ideal of $k \llbracket o_{L} \rrbracket$.

In this situation, [1, Corollary $8.1(\mathrm{~b})]$ implies that $\bar{P}$ must be the zero ideal, provided we can show that the open subgroup $1+p o_{L} \subset o_{L}^{\times}$acts rationally irreducibly on $o_{L}$.

We have to show that every non-trivial $1+p o_{L}$-stable subgroup of $o_{L}$ is open in $o_{L}$. But such a subgroup contains $\left(1+p o_{L}\right) a-a=p a o_{L}$ for some $0 \neq a \in o_{L}$, and is therefore open in $o_{L}$.

Corollary 2.10.9. The restriction of the norm $\|\cdot\|_{\mathfrak{X}}$ on $\Lambda_{L}(\mathfrak{X})$ to $o_{L} \llbracket o_{L} \rrbracket$ coincides with the $\pi$-adic norm on $o_{L} \llbracket o_{L} \rrbracket$ : for any $x \in \pi^{n} o_{L} \llbracket o_{L} \rrbracket \backslash \pi^{n+1} o_{L} \llbracket o_{L} \rrbracket$ we have

$$
\|x\|_{\mathfrak{X}}=\left|\pi^{n}\right| .
$$

Proof. Since $\left\|\pi^{n} y\right\|_{\mathfrak{X}}=\left|\pi^{n}\right| \cdot\|y\|_{\mathfrak{X}}$ for any $y \in o_{L} \llbracket o_{L} \rrbracket$, we may assume that $n=0$. But now since $x \notin \pi o_{L} \llbracket o_{L} \rrbracket$, Lemma 2.10.8 tells us that $\|x\|_{\mathfrak{X}}=1$.

Corollary 2.10.10. The $o_{L}$-module $\Lambda_{L}(\mathfrak{X}) / o_{L} \llbracket o_{L} \rrbracket$ is torsionfree .
Proof. Suppose that $f \in \Lambda_{L}(\mathfrak{X})$ is such that $\pi^{n} f \in o_{L} \llbracket o_{L} \rrbracket$ for some $n \geq$ 0 . Choose $n$ least possible and suppose for a contradiction that $n \geq 1$. Then $\pi^{n} f \in o_{L} \llbracket o_{L} \rrbracket \backslash \pi o_{L} \llbracket o_{L} \rrbracket$, else otherwise we would be able to deduce that $\pi^{n-1} f \in o_{L} \llbracket o_{L} \rrbracket$. Hence $\left\|\pi^{n} f\right\|=1$ by Corollary 2.10.9, which implies that $|\pi|^{-n}=\|f\| \leq 1$. Hence $n=0$.

Corollary 2.10.11. We have $\Lambda_{L}(\mathfrak{X}) \cap\left(L \otimes_{o_{L}} o_{L} \llbracket o_{L} \rrbracket\right)=o_{L} \llbracket o_{L} \rrbracket$.

## 3. The Katz isomorphism

3.1. The $\psi_{q}$-operator. Recall that we denote by $\oplus$ the formal group law of $\mathcal{G}$. Furthermore let $\mathcal{G}_{1}$ denote the group of $\pi$-torsion points of $\mathcal{G}$. Its cardinality is $q$. It coincides with the set of zeros of the Frobenius power series $[\pi](Z)=\varphi(Z)$.

We fix a $\pi$-adically complete and flat $o_{L}$-algebra $S$ in what follows and define an injective $S$-algebra endomorphism $\varphi: S \llbracket Z \rrbracket \rightarrow S \llbracket Z \rrbracket$ by setting

$$
\varphi(F)(Z):=F([\pi](Z)) \quad \text { for all } \quad F(Z) \in S \llbracket Z \rrbracket
$$

## Lemma 3.1.1.

(1) For any $F \in S \llbracket Z \rrbracket$ there is a unique $F_{0} \in S \llbracket Z \rrbracket$ and a unique polynomial $F_{1} \in S[Z]$ of degree $<q$ such that $F=\varphi(Z) F_{0}+F_{1}$.
(2) $\left\{F \in S \llbracket Z \rrbracket: F(\zeta)=0\right.$ for any $\left.\zeta \in \mathcal{G}_{1}\right\}=\varphi(Z) S \llbracket Z \rrbracket$.

Proof. (1). This is a form of Weierstrass division. Since $\varphi(Z) \equiv Z^{q} \bmod$ $\pi o_{L} \llbracket Z \rrbracket$, the proof of [8, VII.3.8 Prop. 5] goes through by replacing the maximal ideal of $S$ in the argument with the ideal $\pi S$.
(2). Since $\varphi(Z)$ vanishes on $\mathcal{G}_{1}$, the inclusion $\supseteq$ is clear. If $F \in S \llbracket Z \rrbracket$ vanishes on $\mathcal{G}_{1}$ then using (1) we may assume that $F \in S[Z]$ with $\operatorname{deg} F<q$. But then $F=0$, which gives the other inclusion.

Using the above Lemma the proof of [10, Lemma 3] remains valid for $S$ and gives

$$
\varphi(S \llbracket Z \rrbracket)=\left\{F \in S \llbracket Z \rrbracket: F(Z)=F(\zeta \oplus Z) \text { for all } \zeta \in \mathcal{G}_{1}\right\}
$$

Since the map $\varphi$ is injective, this description of the image of $\varphi$ implies the existence of a unique $S$-linear endomorphism $\psi_{\text {Col }}$ of $S \llbracket Z \rrbracket$ such that

$$
\varphi\left(\psi_{\mathrm{Col}}(F)(Z)\right)=\sum_{\zeta \in \mathcal{G}_{1}} F(\zeta \oplus Z) \quad \text { for any } F \in S \llbracket Z \rrbracket
$$

Definition 3.1.2. Let $S \llbracket Z \rrbracket_{L}:=S \llbracket Z \rrbracket \otimes_{o_{L}} L$. The $\psi_{q}$-operator is defined by

$$
\psi_{q}:=\frac{1}{q} \psi_{\mathrm{Col}}: S \llbracket Z \rrbracket_{L} \rightarrow S \llbracket Z \rrbracket_{L} .
$$

Note that $\psi_{\text {Col }}\left(\right.$ respectively, $\psi_{q}$ ) preserves $S^{\prime} \llbracket Z \rrbracket\left(\right.$ respectively, $S^{\prime} \llbracket Z \rrbracket_{L}$ ) for any intermediate $\pi$-adically complete and flat $o_{L}$-subalgebra $S^{\prime}$ of $S$. These operators satisfy the following useful Projection Formula.
Lemma 3.1.3. For any $F, G \in S \llbracket Z \rrbracket$ we have $\psi_{q}(F \varphi(G))=\psi_{q}(F) G$.
Proof. We may instead establish the analogous formula for $\psi_{\text {Col }}$. Note that $[\pi](\zeta \oplus Z)=[\pi](\zeta) \oplus[\pi](Z)=[\pi](Z)$ for any $\zeta \in \mathcal{G}_{1}$, since $[\pi](\zeta)=\varphi(\zeta)=0$. Therefore

$$
\begin{aligned}
\varphi\left(\psi_{\mathrm{Col}}(F \varphi(G))\right) & =\sum_{\zeta \in \mathcal{G}_{1}}(F \varphi(G))(\zeta \oplus Z)=\sum_{\zeta} F(\zeta \oplus Z) G([\pi](\zeta \oplus Z)) \\
& =\sum_{\zeta} F(\zeta \oplus Z) G([\pi](Z))=\sum_{\zeta} F(\zeta \oplus Z) \varphi(G) \\
& =\varphi\left(\psi_{\mathrm{Col}}(F)\right) \varphi(G)=\varphi\left(\psi_{\mathrm{Col}}(F) G\right)
\end{aligned}
$$

The result follows because $\varphi$ is injective.
Corollary 3.1.4. We have the fundamental equation $\psi_{q} \circ \varphi=1_{S \llbracket Z \rrbracket_{L}}$.
Proof. Note that $\varphi\left(\psi_{\mathrm{Col}}(1)\right)=q 1$, so $\varphi\left(\psi_{q}(1)\right)=1$ and hence $\psi_{q}(1)=1$. Now set $F=1$ in Lemma 3.1.3.

Next, we remind the reader what the operators $\varphi$ and $\psi_{q}$ do to the special power series $\Delta_{a}=\exp \left(a \Omega \log _{\mathrm{LT}}(Z)\right) \in o_{\infty} \llbracket Z \rrbracket$ from $\S 2.7$.

Lemma 3.1.5. Assume that $S$ is an $o_{\infty}$-algebra and take $a \in o_{L}$.
(1) $\varphi\left(\Delta_{a}\right)=\Delta_{\pi a}$.
(2) $\psi_{q}\left(\Delta_{a}\right)=\delta_{a \in \pi o_{L}} \Delta_{a / \pi}$.

Proof. (1) More generally, whenever $a, b \in o_{L}$ we have

$$
\Delta_{a}([b](Z))=\exp \left(a \Omega \log _{\mathrm{LT}}([b](Z))\right)=\exp \left(a b \Omega \log _{\mathrm{LT}}(Z)\right)=\Delta_{a b}(Z)
$$

Hence $\varphi\left(\Delta_{a}\right)=\Delta_{a}([\pi](Z))=\Delta_{\pi a}$ as claimed.
(2) Using the fact that $\log _{\mathrm{LT}}$ is a formal homomorphism from $\mathcal{G}$ to the formal additive group we compute

$$
\begin{aligned}
\varphi\left(\psi_{\mathrm{Col}}\left(\Delta_{a}\right)\right) & =\sum_{\zeta \in \mathcal{G}_{1}} \Delta_{a}(\zeta \oplus Z)=\sum_{\zeta} \exp \left(a \Omega \log _{\mathrm{LT}}(\zeta \oplus Z)\right) \\
& =\sum_{\zeta} \exp \left(a \Omega\left(\log _{\mathrm{LT}}(\zeta)+\log _{\mathrm{LT}}(Z)\right)\right) \\
& =\left(\sum_{\zeta \in \mathcal{G}_{1}} \Delta_{a}(\zeta)\right) \Delta_{a}
\end{aligned}
$$

Under the Schneider-Teitelbaum isomorphism $\kappa$, the group $\mathcal{G}_{1}$ corresponds to the group of characters $\chi$ of the finite group $o_{L} / \pi_{L} o_{L}$, and, if $\zeta$ corresponds to $\chi$, then $\Delta_{a}(\zeta)=\operatorname{ev}_{\bar{a}}(\chi)=\chi(\bar{a})$, where $\bar{a}:=a+\pi o_{L}$. Hence

$$
\varphi\left(\psi_{\mathrm{Col}}\left(\Delta_{a}\right)\right)=\left(\sum_{\chi} \chi(\bar{a})\right) \Delta_{a}
$$

By column orthogonality of characters of the finite group $o_{L} / \pi_{L}$, we have $\sum_{\chi} \chi(\bar{a})=q \delta_{\bar{a}, \overline{0}}=q \delta_{a \in \pi o_{L}}$. Hence using part (1): $q \varphi\left(\psi_{q}\left(\Delta_{a}\right)\right)=q \delta_{a \in \pi o_{L}} \Delta_{a}=$ $q \delta_{a \in \pi o_{L}} \varphi\left(\Delta_{a / \pi}\right)$. Since $\varphi$ is injective, we deduce that $\psi_{q}\left(\Delta_{a}\right)=\delta_{a \in \pi o_{L}} \Delta_{a / \pi}$ as required.

Write $\mathfrak{m}:=\langle\pi, Z\rangle$ and $A:=S \llbracket Z \rrbracket$.
Lemma 3.1.6. The operators $\varphi$ and $\psi_{\text {Col }}$ on $A$ are $\mathfrak{m}$-adically continuous.
Proof. Since $\varphi(Z) \in\langle Z\rangle$, we see that $\varphi\left(\mathfrak{m}^{n}\right) \subseteq\langle\pi, \varphi(Z)\rangle^{n} \subseteq \mathfrak{m}^{n}$ for all $n \geq 0$. This implies the $\mathfrak{m}$-adic continuity of $\varphi$.

Suppose first that $\mathcal{G}_{1}$ is contained in $S$. Then the $S$-linear maps $A \rightarrow A$ sending $F(Z)$ to $F(Z \oplus \zeta)$ are continuous with respect to $\mathfrak{m}$-adic topology for each $\zeta \in \mathcal{G}_{1}$; hence $\varphi \circ \psi_{\text {Col }}$ is also $\mathfrak{m}$-adically continuous in this case. Let $L_{1}=L\left(\mathcal{G}_{1}\right)$, a finite extension of $L$ and let $S_{1}:=o_{L_{1}} \otimes_{o_{L}} S$. Since $o_{L_{1}}$ is
a free $o_{L}$-module of finite rank, $S_{1}$ is still a $\pi$-adically complete and flat $o_{L^{-}}$ algebra, so letting $A_{1}=S_{1} \llbracket Z \rrbracket$, we see that $\varphi \circ \psi_{\text {Col }}: A_{1} \rightarrow A_{1}$ is $\mathfrak{m} A_{1}$-adically continuous. It follows that $\varphi \circ \psi_{\text {Col }}: A \rightarrow A$ is also $\mathfrak{m}$-adically continuous.

Let $n \geq 0$ be given. Since $\varphi(Z) \equiv Z^{q} \bmod \pi A$, we have $\mathfrak{m}^{q n}=\langle\pi, Z\rangle^{q n} \subseteq$ $\left\langle\pi, Z^{q}\right\rangle^{n}=\langle\pi, \varphi(Z)\rangle^{n}=A \varphi\left(\mathfrak{m}^{n}\right)$. Therefore $\mathfrak{m}^{q n} \cap \varphi(A) \subseteq A \varphi\left(\mathfrak{m}^{n}\right) \cap \varphi(A)=$ $\varphi\left(\mathfrak{m}^{n}\right)$ where this last equation follows from the fact that $\varphi(A)$ admits a direct complement in $A$ as a $\varphi(A)$-module. However since $\varphi \circ \psi_{\text {Col }}$ is continuous, $\varphi \psi_{\text {Col }}\left(\mathfrak{m}^{m}\right) \subseteq \mathfrak{m}^{q n}$ for some $m \geq 0$. Hence

$$
\varphi \psi_{\mathrm{Col}}\left(\mathfrak{m}^{m}\right) \subseteq \mathfrak{m}^{q n} \cap \varphi(A) \subseteq \varphi\left(\mathfrak{m}^{n}\right)
$$

The $\mathfrak{m}$-adic continuity of $\psi_{\text {Col }}$ now follows from the injectivity of $\varphi$.
Lemma 3.1.7. We have $\varphi^{n}\left(a_{n}\right) \rightarrow 0$ in the $\mathfrak{m}$-adic topology on $A$, for any sequence of elements $\left(a_{n}\right)$ contained in $Z A$.

Proof. Since $\varphi(Z) \in \mathcal{G}$ we see that $\varphi(Z) \in Z \mathfrak{m}$. Assume inductively that $\varphi^{n}(Z) \in Z \mathfrak{m}^{n}$; then $\varphi^{n+1}(Z) \in \varphi\left(Z \mathfrak{m}^{n}\right) \subseteq \varphi(Z) \mathfrak{m}^{n} \subseteq Z \mathfrak{m}^{n+1}$, completing the induction. Write $a_{n}=Z b_{n}$ for some $b_{n} \in A$; then $\varphi^{n}\left(a_{n}\right)=\varphi^{n}(Z) \varphi\left(b_{n}\right) \in$ $Z \mathfrak{m}^{n} \subseteq \mathfrak{m}^{n+1}$ for all $n \geq 0$, so $\varphi^{n}\left(a_{n}\right) \rightarrow 0$.

We specialize to the case $S=o_{\infty}$ until the end of $\S 3.1$.
Proposition 3.1.8. Let $f \in D^{L-a n}\left(o_{L}, L\right)$ be such that $\mathcal{F}(f) \in \mathcal{O}(\mathfrak{X})^{\circ}$. Suppose that $\psi_{q}^{n}\left(\mu_{\mathrm{rig}}(f) \Delta_{a}\right) \in o_{\infty} \llbracket Z \rrbracket$ for all $a \in o_{L}$ and $n \geq 0$. Then $f \in o_{L} \llbracket o_{L} \rrbracket$.
Proof. We will show that $\left|f\left(\mathbf{1}_{a+\pi^{n} o_{L}}\right)\right| \leq 1$ for all $a \in o_{L}$ and $n \geq 0$.
By [28, Lemma 4.6(4)], we have

$$
f\left(\mathbf{1}_{a+\pi^{n} o_{L}}\right)=\left(f \delta_{-a}\right)\left(\mathbf{1}_{\pi^{n} o_{L}}\right)
$$

The orthogonality of columns in the character table of the finite group $o_{L} / \pi^{n} o_{L}$ implies that

$$
\mathbf{1}_{\pi^{n} o_{L}}=\frac{1}{q^{n}} \sum_{\left[\pi^{n}\right](z)=0} \kappa_{z}
$$

Hence by ibid., $\left(f \delta_{-a}\right)\left(\mathbf{1}_{\pi^{n} o_{L}}\right)=\frac{1}{q^{n}} \sum_{\left[\pi^{n}\right](z)=0} f(z) \Delta_{-a}(z)$. We now observe that

$$
\frac{1}{q^{n}} \sum_{\left[\pi^{n}\right](z)=0} f(z) \Delta_{-a}(z)=\psi_{q}^{n}\left(\mu_{\text {rig }}(f) \Delta_{-a}\right)(0)
$$

Since $\psi_{q}^{n}\left(\mu_{\text {rig }}(f) \Delta_{-a}\right) \in o_{\infty} \llbracket Z \rrbracket$ by assumption, we have $\left|f\left(\mathbf{1}_{a+\pi^{n} o_{L}}\right)\right| \leq 1$ for all $a \in o_{L}$ and $n \geq 0$, as claimed.

Therefore there exists $g \in o_{L} \llbracket o_{L} \rrbracket$ such that $f=g$ on all $\mathbf{1}_{a+\pi^{n} o_{L}}$. The function $f-g$ is zero on all locally constant functions, and hence on all torsion characters, so that it is divisible by $\log (1+Z)$. Since $f-g$ is bounded and $\log (1+Z)$ is unbounded, this implies that $f=g$.

We can now prove Theorem 1.4.1 from the introduction.
Theorem 3.1.9. We have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if $\psi_{q}\left(\Lambda_{L}(\mathfrak{X})\right) \subset \Lambda_{L}(\mathfrak{X})$.

Proof. The forward implication is clear in view of Lemma 3.1.5(1). For the reverse implication, the given condition means that the image $o_{\infty} \llbracket Z \rrbracket^{G_{L}, *}$ of $\Lambda_{L}(\mathfrak{X})=\mathcal{O}(\mathfrak{X})^{\circ}$ under the bijection $\left(\mu_{\text {rig }} \circ \mathcal{F}^{-1}\right)^{\circ}$ from Corollary 2.9.3 is stable under the $\psi_{q}$-operator. Now the result follows from Proposition 3.1.8.
3.2. The covariant bialgebra of $\mathcal{G}$. Katz $[20, \S 1]$ talks about the "algebra $\operatorname{Diff}(\mathcal{G})$ of all $\mathcal{G}$-invariant $o_{L}$-linear differential operators from $\mathcal{O}(\mathcal{G})$ into itself". Because we are not aware of any place in the literature which adequately deals with invariant differential operators on formal groups, we will instead use the covariant bialgebra of $\mathcal{G}$ which will turn out to be isomorphic to Katz's $\operatorname{Diff}(\mathcal{G})$.

## Definition 3.2.1.

(1) Let $Z_{1} \oplus Z_{2} \in o_{L} \llbracket Z_{1}, Z_{2} \rrbracket$ denote the formal group law defining the formal group $\mathcal{G}$.
(2) Let $U(\mathcal{G})$ denote the set of all $o_{L}$-linear maps from $\mathcal{O}(\mathcal{G})=o_{L} \llbracket Z \rrbracket$ to $o_{L}$ that vanish on some power of the augmentation ideal $Z o_{L} \llbracket Z \rrbracket$. In other words,

$$
U(\mathcal{G})=\underset{\longrightarrow}{\lim } \operatorname{Hom}_{o_{L}}\left(\mathcal{O}(\mathcal{G}) / Z^{n} \mathcal{O}(\mathcal{G}), o_{L}\right) .
$$

We will often use the abbreviation $U:=U(\mathcal{G})$.
(3) For each $f, g \in U(\mathcal{G})$, define the product $f \cdot g$ by the formula $(f \cdot g)(F(Z))=(f \widehat{\otimes} g)\left(F\left(Z_{1} \oplus Z_{2}\right)\right) \quad$ for all $\quad F(Z) \in o_{L} \llbracket Z \rrbracket$.
(4) With this product, $U(\mathcal{G})$ is the covariant bialgebra of $\mathcal{G}$, defined at [17, 36.1.8].
(5) For each $m \geq 0$, let $u_{m} \in U(\mathcal{G})$ be the unique $o_{L}$-linear map that satisfies

$$
u_{m}\left(Z^{n}\right)=\delta_{m n} \quad \text { for all } \quad n \geq 0
$$

(6) Let $\langle-,-\rangle: U(\mathcal{G}) \times \mathcal{O}(\mathcal{G}) \rightarrow o_{L}$ be the evaluation pairing:

$$
\langle f, F\rangle:=f(F)
$$

This covariant bialgebra is also known as the hyperalgebra or the distribution algebra of $\mathcal{G}$. Note that $U(\mathcal{G})$ is a commutative ring: this follows directly from Definition 3.2.1(3), as the formal group law $Z_{1} \oplus Z_{2}$ on the Lubin-Tate formal group $\mathcal{G}$ is commutative. We will now explain the link with Katz's work, using his notation.

## Lemma 3.2.2.

(1) $\left\{u_{n}: n \geq 0\right\}$ is an $o_{L}$-module basis for $U(\mathcal{G})$.
(2) Let $i \geq 0$ and write $\left(Z_{1} \oplus Z_{2}\right)^{i}=\sum_{\substack{n, m \geq 0 \\ n+m \geq i}}^{\infty} \lambda(n, m ; i) Z_{1}^{n} Z_{2}^{m}$ for some

$$
\begin{aligned}
& \lambda(n, m ; i) \in o_{L} \text {. Then for all } n, m \geq 0 \text { we have } \\
& \qquad u_{n} \cdot u_{m}=\sum_{k=0}^{n+m} \lambda(n, m ; k) u_{k}
\end{aligned}
$$

(3) Let $s$ be a variable. The map $L[s] \rightarrow U(\mathcal{G}) \otimes_{o_{L}} L$ which sends $s$ to $u_{1} \otimes 1$ is an isomorphism of positively filtered L-algebras.
Proof. (1) This is clear because $Z^{n} o_{L} \llbracket Z \rrbracket=o_{L} Z^{n} \oplus Z^{n+1} o_{L} \llbracket Z \rrbracket$ for any $n \geq 0$.
(2) We compute that for every $n, m, i \geq 0$ we have

$$
\begin{aligned}
\left(u_{n} \cdot u_{m}\right)\left(Z^{i}\right)=\left(u_{n} \widehat{\otimes} u_{m}\right) & \left(\left(Z_{1} \oplus Z_{2}\right)^{i}\right) \\
& =\left(u_{n} \widehat{\otimes} u_{m}\right)\left(\sum_{\substack{a, b \geq 0 \\
a+b \geq i}}^{\infty} \lambda(a, b ; i) Z_{1}^{a} Z_{2}^{b}\right)=\lambda(n, m ; i)
\end{aligned}
$$

Because $\sum_{k=0}^{n+m} \lambda(n, m ; k) u_{k}$ also sends $Z^{i}$ to $\lambda(n, m ; i)$, it must be equal to $u_{n} \cdot u_{m}$.
(3) From (2) we see that the $o_{L}$-submodule $U(\mathcal{G})_{n}$ of $U(\mathcal{G})$ generated by $\left\{u_{i}: 0 \leq i \leq n\right\}$ defines an algebra filtration on $U(\mathcal{G})$ :

$$
U(\mathcal{G})_{n} \cdot U(\mathcal{G})_{m} \subseteq U(\mathcal{G})_{n+m} \quad \text { for all } \quad n, m \geq 0
$$

The associated graded ring is the free $o_{L}$-module with basis $\left\{\operatorname{gr} u_{n}: n \geq 0\right\}$. Since $Z_{1} \oplus Z_{2} \equiv Z_{1}+Z_{2} \bmod \left(Z_{1}, Z_{2}\right)^{2}$ by part (2), we see that for any $i \geq 0$ we have

$$
\begin{aligned}
& \sum_{\substack{n, m \geq 0 \\
n+m \geq i}}^{\infty} \lambda(n, m ; i) Z_{1}^{n} Z_{2}^{m}=\left(Z_{1} \oplus Z_{2}\right)^{i} \\
& \equiv\left(Z_{1}+Z_{2}\right)^{i}=\sum_{n+m=i}\binom{i}{n} Z_{1}^{n} Z_{2}^{m} \bmod \left(Z_{1}, Z_{2}\right)^{i+1}
\end{aligned}
$$

Equating the coefficient of $Z_{1}^{n} Z_{2}^{i-n}$ shows that $\lambda(n, i-n ; i)=\binom{i}{n}$ whenever $0 \leq n \leq i$ :

$$
\lambda(n, m ; n+m)=\binom{n+m}{n} \quad \text { for any } \quad n, m \geq 0
$$

Hence from (2) we see that the multiplication in $\operatorname{gr} U(\mathcal{G})$ is given by

$$
\left(\operatorname{gr} u_{n}\right) \cdot\left(\operatorname{gr} u_{m}\right)=\binom{n+m}{n} \operatorname{gr} u_{n+m}
$$

The same formulas hold in $\operatorname{gr}\left(U(\mathcal{G}) \otimes_{o_{L}} L\right)$. Induction on $n$ shows that we have $\left(\operatorname{gr} u_{1}\right)^{n}=n!\operatorname{gr} u_{n}$ for all $n \geq 0$. Since $L$ has characteristic zero, we see that $\operatorname{gr}\left(U(\mathcal{G}) \otimes_{o_{L}} L\right)$ is generated by $\operatorname{gr} u_{1}$ as an $L$-algebra. The result follows.

We will henceforth identify $U(\mathcal{G}) \otimes_{o_{L}} L$ with the polynomial ring $L[s]$. Recall the polynomials $P_{n}(Y) \in L[Y]$ from [28, Definition 4.1], which are defined by the following formal expansion:

$$
\exp \left(Y \log _{\mathrm{LT}}(Z)\right)=\sum_{m=0}^{\infty} P_{m}(Y) Z^{m}
$$

Lemma 3.2.3. For every $n \geq 0$, we have $u_{n}=P_{n}\left(u_{1}\right)$ inside $U(\mathcal{G}) \otimes_{o_{L}} L$.

Proof. The structure constants of Katz's algebra $\operatorname{Diff}(\mathcal{G})$ are the same as the ones in $U(\mathcal{G})$ by $[20,(1.2)]$ and Lemma 3.2.2(2). So the $o_{L}$-linear map that sends $D(n) \in \operatorname{Diff}(\mathcal{G})$ to $u_{n} \in U(\mathcal{G})$ is an $o_{L}$-algebra isomorphism. Comparing [20, Corollary 1.8] with [28, Definition 4.1] shows that $D(n)=P_{n}(D(1))$ in $\operatorname{Diff}(\mathcal{G}) \otimes_{o_{L}} L$ for all $n \geq 0$. The result follows by applying the algebra isomorphism $\operatorname{Diff}(\mathcal{G}) \rightarrow U(\mathcal{G})$ established above.

Of course in the context of affine group schemes, this isomorphism between the algebra of left-invariant differential operators on the group scheme and the distribution algebra of the group scheme is the well known 'Invariance Theorem', [12, Chapter II, §4, Theorem 6.6].

Next, we consider the action of the monoid $o_{L}$ on the formal group $\mathcal{G}$. The covariant bialgebra construction is functorial in $\mathcal{G}$ : if $\varphi: \mathcal{G} \rightarrow \mathcal{H}$ is a morphism of formal groups, then $U(\varphi): U(\mathcal{G}) \rightarrow U(\mathcal{H})$ is the morphism of $o_{L}$-bialgebras which is the transpose to the $o_{L}$-algebra homomorphism $\varphi^{*}: \mathcal{O}(\mathcal{H}) \rightarrow \mathcal{O}(\mathcal{G})$ induced by $\varphi$. Using the evaluation pairing, we have the following formula which defines this action:

$$
\begin{equation*}
\langle U(\varphi)(f), F\rangle=\left\langle f, \varphi^{*}(F)\right\rangle \quad \text { for all } \quad f \in U(\mathcal{G}), F \in \mathcal{O}(\mathcal{G}) . \tag{4}
\end{equation*}
$$

Definition 3.2.4. Take $a \in o_{L}$.
(1) Let $[a]: \mathcal{G} \rightarrow \mathcal{G}$ be the action of $a$ on $\mathcal{G}$.
(2) Write $a \cdot f:=U([a])(f)$ for all $f \in U(\mathcal{G})$.

The $o_{L}$-algebra endomorphism $U([a])$ of $U(\mathcal{G})$ extends to an $L$-algebra endomorphism $U([a]) \otimes 1$ of $U(\mathcal{G}) \otimes_{o_{L}} L=L[s]$. What does this action do to the generator $s$ of $L[s]$ ?

Lemma 3.2.5. We have $a \cdot s=$ as for all $a \in o_{L}$.
Proof. We know that $[a](Z) \equiv a Z \bmod Z^{2} o_{L} \llbracket Z \rrbracket$. Hence

$$
\left\langle U([a])\left(u_{1}\right), Z^{n}\right\rangle=\left\langle u_{1},[a](Z)^{n}\right\rangle=a \delta_{n, 1}=\left\langle a u_{1}, Z^{n}\right\rangle \quad \text { for all } \quad n \geq 0
$$

using Definition 3.2.1(5). Hence $a \cdot u_{1}=a u_{1}$ and so $a \cdot s=a s$.
Corollary 3.2.6. For each $j \geq i \geq 0$ and $a \in o_{L}$ there exists $\sigma_{i j}(a) \in o_{L}$ such that

$$
a \cdot u_{j}=P_{j}(a s)=\sum_{i=0}^{j} \sigma_{i j}(a) P_{i}(s)=\sum_{i=0}^{j} \sigma_{i j}(a) u_{i} .
$$

Proof. It follows from Lemma 3.2.5 that the $L$-algebra endomorphisms of $L[s]$ given by $s \mapsto a s$ preserve the $o_{L}$-subalgebra $U(\mathcal{G}) \subset L[s]$. Hence $a \cdot u_{j}=P_{j}(a s)$ lies in $U(\mathcal{G})$ for all $a \in o_{L}$ and all $j \geq 0$. But $U(\mathcal{G})$ has $\left\{u_{i}: i \geq 0\right\}$ as an $o_{L^{-}}$ module basis by Lemma 3.2.2(a), so $P_{j}(a s)$ must be an $o_{L}$-linear combination of these $u_{i}$ 's. On the other hand, $P_{j}(s)$ is a polynomial of degree $j$ in $s$, therefore so is $P_{j}(a s)$; because $\operatorname{deg} P_{i}=i$ for each $i$ it follows that $P_{j}(a s)$ is an $L$-linear combination of $P_{0}(s), \cdots, P_{j}(s)$ only.

We now introduce a coefficient ring $S$, which we assume to be a $\pi$-adically complete $o_{L}$-algebra. For every $S$-module $M$, let $M^{*}:=\operatorname{Hom}_{S}(M, S)$ be the $S$-module of $S$-linear functionals on $M$. We will need to work with a larger class of $S$-linear functionals on $S \llbracket Z \rrbracket$ than those arising from $U(\mathcal{G})$, namely the continuous ones.

Definition 3.2.7. We say that $\lambda \in S \llbracket Z \rrbracket^{*}$ is continuous if it is continuous with respect to the $\langle\pi, Z\rangle$-adic topology on $S \llbracket Z \rrbracket$, and the $\pi$-adic topology on $S$. Let $S \llbracket Z \rrbracket_{\text {cts }}^{*}$ denote the set of these continuous $S$-linear functionals on $S \llbracket Z \rrbracket$.

Explicitly $\lambda \in S \llbracket Z \rrbracket^{*}$ is continuous if and only if for all $n \geq 0$ there exists $m \geq 0$ such that $\lambda\left(\langle\pi, Z\rangle^{m}\right) \subseteq \pi^{n} S$.

Consider now the base change $U\left(\mathcal{G}_{S}\right):=U(\mathcal{G}) \otimes_{o_{L}} S$, and its $\pi$-adic completion

$$
\widehat{U\left(\mathcal{G}_{S}\right)}=\lim _{\rightleftarrows} U(\mathcal{G}) \otimes_{o_{L}}\left(S / \pi^{n} S\right)
$$

Since $\left\{u_{m}: m \geq 0\right\}$ is an $o_{L}$-module basis for $U(\mathcal{G})$ by Lemma 3.2.2(1), we see that $\widehat{U\left(\mathcal{G}_{S}\right)}$ has the following description:

$$
\begin{equation*}
\widehat{U\left(\mathcal{G}_{S}\right)}=\left\{\sum_{m=0}^{\infty} a_{m} u_{m}: \quad a_{m} \in S, \lim _{m \rightarrow \infty} a_{m}=0\right\} \tag{5}
\end{equation*}
$$

Here we equip $S$ with the $\pi$-adic topology.

## Lemma 3.2.8.

(1) The pairing $\langle-,-\rangle: U(\mathcal{G}) \times o_{L} \llbracket Z \rrbracket \rightarrow o_{L}$ extends to an $S$-bilinear pairing

$$
\langle-,-\rangle: \widehat{U\left(\mathcal{G}_{S}\right)} \times S \llbracket Z \rrbracket \rightarrow S
$$

(2) For each $u \in \widehat{U\left(\mathcal{G}_{S}\right)}$, the $S$-linear map $\langle u,-\rangle: S \llbracket Z \rrbracket \rightarrow S$ is continuous.
(3) The map $\widehat{U\left(\mathcal{G}_{S}\right)} \rightarrow S \llbracket Z \rrbracket_{\text {cts }}^{*}, u \mapsto\langle u,-\rangle$, is an $S$-linear bijection.
(4) The map $S \llbracket Z \rrbracket \rightarrow{\widehat{U\left(\mathcal{G}_{S}\right)}}^{*}, F \mapsto\langle-, F\rangle$, is an $S$-linear bijection.

Proof. (1) Let $u=\sum_{m=0}^{\infty} a_{m} u_{m} \in \widehat{U\left(\mathcal{G}_{S}\right)}, F=\sum_{n=0}^{\infty} F_{n} Z^{n} \in S \llbracket Z \rrbracket$ and define $\langle u, F\rangle=\sum_{m=0}^{\infty} a_{m} F_{m}$. This series converges in $S$ because $a_{m} \rightarrow 0$ as $m \rightarrow \infty$ and because $S$ is assumed to be $\pi$-adically complete.
(2) Let $n \geq 0$ and write $u=\sum_{m=0}^{\infty} a_{m} u_{m}$ with $a_{m} \rightarrow 0$. Then for some $r \geq 0$, $a_{m} \in \pi^{n} S$ for all $m \geq r$. Hence $\langle u,-\rangle$ sends the ideal $\left\langle\pi^{n}, Z^{r}\right\rangle$ of $S \llbracket Z \rrbracket$ into $\pi^{n} S$. Since $\langle\pi, Z\rangle^{n+r} \subseteq\left\langle\pi^{n}, Z^{r}\right\rangle$, we conclude that $\langle u,-\rangle$ is $\langle\pi, Z\rangle$-adically continuous.
(3) The injectivity of $u \mapsto\langle u,-\rangle$ follows by evaluating on each $Z^{n}$. Now let $\lambda \in S \llbracket Z \rrbracket_{\text {cts }}^{*}$ and define $a_{m}:=\lambda\left(Z^{m}\right) \in S$ for each $m \geq 0$. Since $\lambda$ is $\langle\pi, Z\rangle$-adically continuous, for each $n \geq 0$ we can find some $r \geq 0$ such that $\lambda\left(\langle\pi, Z\rangle^{r}\right) \subseteq \pi^{n} S$. Then $a_{m} \in \pi^{n} S$ for all $m \geq r$ which implies that $a_{m} \rightarrow 0$
as $m \rightarrow \infty$. Hence $u:=\sum_{m=0}^{\infty} a_{m} u_{m}$ is an element of $\widehat{U\left(\mathcal{G}_{S}\right)}$ and $\langle u,-\rangle-\lambda$ vanishes on $S[Z]$ by construction. Since this difference is continuous and since $S[Z]$ is dense in $S \llbracket Z \rrbracket$ with respect to the $\langle\pi, Z\rangle$-adic topology, we conclude that $\lambda=\langle u,-\rangle$.
(4) Again, the injectivity of $F \mapsto\langle-, F\rangle$ follows from $\left\langle u_{m}, F\right\rangle=F_{m}$. Given an $S$-linear map $\lambda: U\left(\mathcal{G}_{S}\right) \rightarrow S$, let $F:=\sum_{n=0}^{\infty} \lambda\left(u_{n}\right) Z^{n}$. Then $\left\langle u_{m}, F\right\rangle=\lambda\left(u_{m}\right)$ for all $m \geq 0$. Since the $u_{m}$ span $U\left(\mathcal{G}_{S}\right)$ as an $S$-module, $\lambda=\langle-, F\rangle$.

As an immediate consequence of Lemma 3.2.8, we have the following

## Corollary $\mathbf{3 . 2 . 9}$.

(1) For every continuous $S$-linear $\alpha: S \llbracket Z \rrbracket \rightarrow S \llbracket Z \rrbracket$ there exists a unique $S$-linear map $\alpha^{*}: \widehat{U\left(\mathcal{G}_{S}\right)} \rightarrow \widehat{U\left(\mathcal{G}_{S}\right)}$ such that

$$
\left\langle\alpha^{*} u, F\right\rangle=\langle u, \alpha F\rangle \quad \text { for all } \quad u \in \widehat{U\left(\mathcal{G}_{S}\right)}, F \in S \llbracket Z \rrbracket .
$$

(2) For every $S$-linear $\beta: \widehat{U\left(\mathcal{G}_{S}\right)} \rightarrow \widehat{U\left(\mathcal{G}_{S}\right)}$ there exists a unique $S$-linear map $\beta^{*}: S \llbracket Z \rrbracket \rightarrow S \llbracket Z \rrbracket$ such that

$$
\langle u, \beta F\rangle=\left\langle\beta^{*} u, F\right\rangle \quad \text { for all } \quad u \in \widehat{U\left(\mathcal{G}_{S}\right)}, F \in S \llbracket Z \rrbracket .
$$

We also extend this $S$-linear pairing to an $S_{L}:=S \otimes_{o_{L}} L$-linear pairing

$$
\langle-,-\rangle: \widehat{U\left(\mathcal{G}_{S}\right)}{ }_{L} \times S \llbracket Z \rrbracket_{L} \rightarrow S_{L}
$$

which we will use without further mention. Observe that there is a natural $o_{L}$-linear map $\widehat{U} \rightarrow \widehat{U\left(\mathcal{G}_{S}\right)}$ for any $o_{L}$-algebra $S$.

Lemma 3.2.10. The restriction map ${\widehat{U\left(\mathcal{G}_{S}\right)}}^{*} \rightarrow \operatorname{Hom}_{o_{L}}(\widehat{U}, S)$ is an $S$-linear isomorphism.

Proof. Let $\lambda: \widehat{U\left(\mathcal{G}_{S}\right)} \rightarrow S$ be an $S$-linear map whose restriction to $\widehat{U}$ is zero. Then in particular $\lambda\left(u_{m}\right)=0$ for all $m \geq 0$, so $\lambda$ vanishes on all finite sums of the form $\sum_{m=0}^{n} a_{m} u_{m} \in \widehat{U\left(\mathcal{G}_{S}\right)}$ with $a_{m} \in S$. These sums are $\pi$-adically dense in $\widehat{U\left(\mathcal{G}_{S}\right)}$ in view of (5), so for any $x \in \widehat{U\left(\mathcal{G}_{S}\right)}, \lambda(x) \in \bigcap_{n=0}^{\infty} \pi^{n} S$. Since we're assuming that $S$ is $\pi$-adically complete, this intersection is zero, so $\lambda=0$ and the restriction map in question is injective.

Suppose now $\lambda: \widehat{U} \rightarrow S$ is an $o_{L}$-linear map. Using the description of $\widehat{U\left(\mathcal{G}_{S}\right)}$ given in (5), we extend it to an $S$-linear map $\tilde{\lambda}: \widehat{U\left(\mathcal{G}_{S}\right)} \rightarrow S$ by setting for every zero-sequence $\left(a_{m}\right)$ in $S$

$$
\tilde{\lambda}\left(\sum_{m=0}^{\infty} a_{m} u_{m}\right):=\sum_{m=0}^{\infty} a_{m} \lambda\left(u_{m}\right)
$$

Since $\lim _{m \rightarrow \infty} a_{m}=0$ in $S$, the series on the right hand side converges in $S$ because $S$ is assumed to be $\pi$-adically complete. So, $\tilde{\lambda}$ is a well-defined $S$-linear map extending $\lambda$.
3.3. Gal-continuous functions. Let $\mathcal{C}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ be the $\mathbb{C}_{p}$-Banach space of all continuous $\mathbb{C}_{p}$-valued functions on $o_{L}$, equipped with the supremum norm. The unit ball of this $\mathbb{C}_{p}$-Banach space is the $o_{\mathbb{C}_{p}}$-submodule $\mathcal{C}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$ of continuous $o_{\mathbb{C}_{p}}$-valued functions.

Definition 3.3.1. A function $f \in \mathcal{C}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ is said to be Gal-continuous if

$$
\sigma(f(a))=f(a \tau(\sigma)) \quad \text { for all } \quad a \in o_{L}, \sigma \in G_{L}
$$

We write $C:=\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ for the set of all Gal-continuous $\mathbb{C}_{p}$-valued functions.

Evidently $\mathcal{C}:=\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)=C \cap \mathcal{C}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$ forms an $o_{L}$-lattice in $C$.
Lemma 3.3.2. Let $f \in C$. Then $\operatorname{im} f \subseteq L_{\infty}$, and $\operatorname{im} f \subseteq o_{\infty}$ if $f \in \mathcal{C}$.
Proof. By Definition 3.3.1, we have $\operatorname{im} f \subseteq \mathbb{C}_{p}^{\operatorname{ker} \tau}$ for all $f \in C$, and $\operatorname{im} f \subseteq$ $o_{\mathbb{C}_{p}}^{\text {ker } \tau}$ for all $f \in \mathcal{C}$. But $\mathbb{C}_{p}^{\mathrm{ker} \tau}=L_{\infty}$ and $o_{\mathbb{C}_{p}}^{\mathrm{ker} \tau}=o_{\infty}$ by Lemma 2.7.2.
Lemma 3.3.3. For each $u \in \widehat{U}$, the function $a \mapsto \mathcal{K}(u)(a):=\left\langle u, \Delta_{a}\right\rangle$ on $o_{L}$ is Gal-continuous.

Proof. By definition, $\mathcal{K}(u)$ is the composition of $\mu_{\mid o_{L}}: o_{L} \rightarrow o_{\infty} \llbracket Z \rrbracket^{\times}$with the restriction of the linear functional $\langle u,-\rangle: o_{\infty} \llbracket Z \rrbracket \rightarrow o_{\infty}$ to $o_{\infty} \llbracket Z \rrbracket^{\times}$. This linear functional is continuous by Lemma 3.2.8(3), so to establish the continuity of $\mathcal{K}(u)$ it remains to show that $\mu_{\mid o s_{L}}$ is continuous. Since $\mu_{\mid o_{L}}$ is a group homomorphism, it is enough to show that it is continuous at the identity element 0 of $o_{L}$. Let $n>0$ and consider the basic open neighbourhood $1+$ $\langle\pi, Z\rangle^{n}$ of $1 \in o_{\infty} \llbracket Z \rrbracket^{\times}$. Since $\varphi^{n}(Z) \rightarrow 0$ as $n \rightarrow \infty$ in $o_{\infty} \llbracket Z \rrbracket$ by Lemma 3.1.7, we can find $m \geq 0$ such that $\varphi^{m}(Z) \in\langle\pi, Z\rangle^{n}$. Hence for any $a \in o_{L}$, using Lemma 3.1.5 we calculate

$$
\Delta_{\pi^{m} a}-\Delta_{0}=\varphi^{m}\left(\Delta_{a}-1\right) \in \varphi^{m}\left(Z o_{\infty} \llbracket Z \rrbracket\right) \subseteq \varphi^{m}(Z) o_{\infty} \llbracket Z \rrbracket \subseteq\langle\pi, Z\rangle^{n}
$$

Hence $\mu_{\mid o_{L}}$ is continuous as required.
Now let $\sigma \in G_{L}$; since $\Delta_{a} \in o_{\infty} \llbracket Z \rrbracket$ is invariant for the $*$-action of $G_{L}$ on $o_{\infty} \llbracket Z \rrbracket$, we know that $\sigma\left(\Delta_{a}\right)=\Delta_{a}([\tau(\sigma)](Z))=\Delta_{a \tau(\sigma)}$ for any $a \in o_{L}$. Since $u \in \widehat{U}$, we have for any $a \in o_{L}$

$$
\sigma(\mathcal{K}(u)(a))=\sigma\left(\left\langle u, \Delta_{a}\right\rangle\right)=\left\langle u, \sigma\left(\Delta_{a}\right)\right\rangle=\left\langle u, \Delta_{a \tau(\sigma)}\right\rangle=\mathcal{K}(u)(a \tau(\sigma))
$$

Hence $\mathcal{K}(u)$ is indeed Gal-continuous.

## Definition 3.3.4.

(1) Define the Katz map $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$ as follows:

$$
\mathcal{K}(u)(a)=\left\langle u, \Delta_{a}\right\rangle \quad \text { for any } \quad u \in \widehat{U}, a \in o_{L}
$$

(2) Define $\mathcal{K}_{1}: \widehat{U} \rightarrow o_{\infty}$ by $\mathcal{K}_{1}=\mathrm{ev}_{1} \circ \mathcal{K}$.
(3) Define $\psi_{C}: C \rightarrow C$ by the rule

$$
\psi_{C}(f)(a)=\delta_{a \in \pi o_{L}} f(a / \pi) \quad \text { for all } \quad a \in o_{L}
$$

The operator $\psi_{\mathcal{C}}: \mathcal{C} \rightarrow \mathcal{C}$ is by definition the restriction of $\psi_{C}$ to $\mathcal{C}$.
(4) Define $\varphi_{C}: C \rightarrow C$ by the rule

$$
\varphi_{C}(f)(a)=f(\pi a) \quad \text { for all } \quad a \in o_{L}
$$

The operator $\varphi_{\mathcal{C}}: \mathcal{C} \rightarrow \mathcal{C}$ is by definition the restriction of $\varphi_{C}$ to $\mathcal{C}$.
Using his notation, Katz has already observed [19, p. 99] the following fact.
Lemma 3.3.5. The map $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$ is an $o_{L}$-algebra homomorphism.
Proof. By the definition of the Lubin-Tate logarithm, we have

$$
\log _{L T}\left(Z_{1} \oplus Z_{2}\right)=\log _{L T}\left(Z_{1}\right)+\log _{L T}\left(Z_{2}\right)
$$

from which it follows that for all $a \in o_{L}$ we have

$$
\Delta_{a}\left(Z_{1} \oplus Z_{2}\right)=\Delta_{a}\left(Z_{1}\right) \Delta_{a}\left(Z_{2}\right)
$$

Using Definition 3.2.1(3), we can then compute that for any $u, v \in U$ and any $a \in o_{L}$ we have

$$
\begin{aligned}
\mathcal{K}(u \cdot v)(a)=\left\langle u \cdot v, \Delta_{a}(Z)\right\rangle & =(u \widehat{\otimes} v)\left(\Delta_{a}\left(Z_{1} \oplus Z_{2}\right)\right) \\
& =(u \widehat{\otimes} v)\left(\Delta_{a}\left(Z_{1}\right) \Delta_{a}\left(Z_{2}\right)\right)=\mathcal{K}(u)(a) \mathcal{K}(u)(v) .
\end{aligned}
$$

Hence $\mathcal{K}(u \cdot v)=\mathcal{K}(u) \mathcal{K}(v)$ for all $u, v \in U$ and the result follows easily.
Now we recall the coefficient ring $S$ that was introduced before Definition 3.2.7. Applying the $S$-linear duality functor

$$
(-)^{*}:=\operatorname{Hom}_{o_{L}}(-, S)
$$

to the Katz map $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$ gives us the dual Katz map

$$
\mathcal{K}^{*}: \mathcal{C}^{*} \rightarrow \widehat{U}^{*}
$$

defined on the space of $S$-valued Galois measures $\mathcal{C}^{*}=\operatorname{Hom}_{o_{L}}(\mathcal{C}, S)$. We identify $\widehat{U}^{*}=\operatorname{Hom}_{o_{L}}(\widehat{U}, S)$ with $S \llbracket Z \rrbracket$ using Lemma 3.2.10 and Lemma 3.2.8(4); then $\mathcal{K}^{*}: \mathcal{C}^{*} \rightarrow S \llbracket Z \rrbracket$ is given explicitly by

$$
\begin{equation*}
\left.\left\langle u_{m}, \mathcal{K}^{*}(\lambda)\right\rangle=\lambda\left(P_{m}(-\Omega)\right)\right) \quad \text { for all } \quad \lambda \in \mathcal{C}^{*}, m \geq 0 \tag{6}
\end{equation*}
$$

After Lemma 3.1.6 and Corollary 3.2.9 applied with $S=o_{L}$, we have at our disposal the dual $o_{L}$-linear endomorphisms $\psi_{\text {Col }}^{*}$ and $\varphi^{*}$ of $\widehat{U}$.
Lemma 3.3.6. We have $\mathcal{K} \varphi^{*}=\varphi_{\mathcal{C}} \mathcal{K}$ and $\mathcal{K} \psi_{\text {Col }}^{*}=q \psi_{\mathcal{C}} \mathcal{K}$.
Proof. Let $u \in \widehat{U}_{L}$ and $a \in o_{L}$. Then using Lemma 3.1.5, we have

$$
\begin{aligned}
\mathcal{K}\left(\psi_{\mathrm{Col}}^{*}(u)\right)(a)= & \left\langle\psi_{\mathrm{Col}}^{*}(u), \Delta_{a}\right\rangle=\left\langle u, \psi_{\mathrm{Col}}\left(\Delta_{a}\right)\right\rangle=\left\langle u, q \psi_{q}\left(\Delta_{a}\right)\right\rangle \\
& =q\left\langle u, \delta_{a \in \pi o_{L}} \Delta_{a / \pi}\right\rangle=q \delta_{a \in \pi o_{L}} \mathcal{K}(u)(a / \pi)=q \psi_{\mathcal{C}}(\mathcal{K}(u))(a)
\end{aligned}
$$

which gives the second equation. The first equation is proved in a similar manner.

Corollary 3.3.7. We have $\mathcal{K}^{*} \varphi_{\mathcal{C}}^{*}=\varphi \mathcal{K}^{*}$ and $\mathcal{K}^{*} \psi_{\mathcal{C}}^{*}=\psi_{q} \mathcal{K}^{*}$.
Proof. We apply the $S$-linear duality functor $(-)^{*}=\operatorname{Hom}_{o_{L}}(-, S)$ to the equations from Lemma 3.3.6. Using Lemma 3.2.8, we see that

$$
\mathcal{K}^{*} \varphi_{\mathcal{C}}^{*}=\left(\varphi_{\mathcal{C}} \mathcal{K}\right)^{*}=\left(\mathcal{K} \varphi^{*}\right)^{*}=\varphi^{* *} \mathcal{K}^{*}=\varphi \mathcal{K}^{*}
$$

and similarly,

$$
q \mathcal{K}^{*} \psi_{\mathcal{C}}^{*}=\left(q \psi_{\mathcal{C}} \mathcal{K}\right)^{*}=\left(\mathcal{K} \psi_{\mathrm{Col}}^{*}\right)^{*}=\psi_{\mathrm{Col}} \mathcal{K}^{*}=q \psi_{q} \mathcal{K}^{*}
$$

Now divide both sides by $q$.
Lemma 3.3.8. We have $\psi_{q} \circ \mathcal{K}_{1}^{*}=0$.
Proof. Corollary 3.3.7 gives $\psi_{q} \mathcal{K}_{1}^{*}=\psi_{q} \mathcal{K}^{*} \mathrm{ev}_{1}^{*}=\mathcal{K}^{*} \psi_{\mathcal{C}}^{*} \mathrm{ev}_{1}^{*}=\left(\mathrm{ev}_{1} \psi_{\mathcal{C}} \mathcal{K}\right)^{*}$. But $\mathrm{ev}_{1} \psi_{\mathcal{C}}(f)=\psi_{\mathcal{C}}(f)(1)=0$ for any $f \in \mathcal{C}$ by Definition 3.3.4(3), because $\delta_{1 \in \pi o_{L}}=0$.

Proposition 3.3.9. If $\mathcal{K}$ is injective and $\tau$ is surjective, then $q \operatorname{ker} \mathcal{K}_{1} \subseteq$ $\psi_{\text {Col }}^{*}(\widehat{U})$.
Proof. In this proof we may assume $S=o_{L}$. Suppose that $\mathrm{ev}_{1} \circ \mathcal{K}(u)=0$ for some $u \in \widehat{U}$. Then $\mathcal{K}(u)$ is zero on $o_{L}^{\times}$because $\tau$ is surjective and because $\mathcal{K}(u)$ is Gal-continuous by Lemma 3.3.3. Hence $\mathcal{K}(u)=\psi_{\mathcal{C}} \varphi_{\mathcal{C}} \mathcal{K}(u)$. But $q \psi_{\mathcal{C}} \varphi_{\mathcal{C}} \mathcal{K}(u)=q \psi_{\mathcal{C}} \mathcal{K} \varphi^{*}(u)=\mathcal{K} \psi_{\text {Col }}^{*} \varphi^{*}(u)$ by Lemma 3.3.6, so $\mathcal{K}(q u-$ $\left.\psi_{\text {Col }}^{*} \varphi^{*}(u)\right)=0$. Since $\mathcal{K}$ is injective by assumption, $q u=\psi_{\text {Col }}^{*}\left(\varphi^{*}(u)\right) \in$ $\psi_{\text {Col }}^{*}(\widehat{U})$.

Proposition 3.3.10. Suppose that $\tau: G_{L} \rightarrow o_{L}^{\times}$and $\mathcal{K}_{1}: \widehat{U} \rightarrow o_{\infty}$ are both surjective, and that $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$ is injective. Then

$$
\mathcal{K}_{1}^{*}: o_{\infty}^{*} \rightarrow S \llbracket Z \rrbracket^{\psi_{q}=0}
$$

is an $S$-linear bijection.
Proof. The image of $\mathcal{K}^{*}: o_{\infty}^{*} \rightarrow S \llbracket Z \rrbracket$ is contained in $S \llbracket Z \rrbracket^{\psi_{q}=0}$ by Lemma 3.3.8. If $\mathcal{K}_{1}^{*}(\ell)=0$ for some $\ell \in o_{\infty}^{*}$, then $\ell \circ \mathcal{K}_{1}=0$ so $\ell\left(\mathcal{K}_{1}(\widehat{U})\right)=0$. But $\mathcal{K}_{1}(\widehat{U})=o_{\infty}$ by assumption, so $\ell=0$. Hence $\mathcal{K}_{1}^{*}$ is injective and it remains to prove it is also surjective.

Take some $F \in S \llbracket Z \rrbracket^{\psi_{q}=0}$ and let $\ell:=\langle-, F\rangle \in{\widehat{U\left(\mathcal{G}_{S}\right)}}^{*} \cong \widehat{U}^{*}$ be the $S$ valued $o_{L}$-linear functional on $\widehat{U}$ given by Lemma 3.2.10 and Lemma 3.2.8(4). Then since $\psi_{\text {Col }}(F)=q \psi_{q}(F)=0$,

$$
0=\left\langle u, \psi_{\mathrm{Col}}(F)\right\rangle=\left\langle\psi_{\mathrm{Col}}^{*}(u), F\right\rangle=\ell\left(\psi_{\mathrm{Col}}^{*}(u)\right) \quad \text { for all } \quad u \in \widehat{U}
$$

So, $\ell$ vanishes on $\psi_{\text {Col }}^{*}(\widehat{U})$ and hence also on $q \operatorname{ker} \mathcal{K}_{1}$ by Proposition 3.3.9. Since $o_{L}$ has no $q$-torsion, we see that $\ell$ is zero on $\operatorname{ker} \mathcal{K}_{1}$. Hence $\ell$ descends to an $S$-valued $o_{L}$-linear functional on $\widehat{U} / \operatorname{ker} \mathcal{K}_{1}$. But this quotient is isomorphic
to $o_{\infty}$ by assumption. So, we get a well-defined $o_{L}$-linear form $\bar{\ell}: o_{\infty} \rightarrow S$ such that $\bar{\ell}\left(\mathcal{K}_{1}(u)\right)=\ell(u)$ for all $u \in \widehat{U}$. Then

$$
\left\langle u, \mathcal{K}_{1}^{*}(\bar{\ell})\right\rangle=\bar{\ell}\left(\mathcal{K}_{1}(u)\right)=\ell(u)=\langle u, F\rangle \quad \text { for all } \quad u \in \widehat{U}
$$

which implies that $F=\mathcal{K}_{1}^{*}(\bar{\ell})$ by Lemma 3.2.8(4). Hence $\mathcal{K}_{1}^{*}$ is surjective.
We make the following tentative
Conjecture 3.3.11. The map $\mathcal{K}_{1}: \widehat{U} \rightarrow o_{\infty}$ is surjective and the map $\mathcal{K}$ : $\widehat{U} \rightarrow \mathcal{C}$ is injective whenever $\tau$ is surjective.
3.4. The largest $\psi_{q}$-stable $o_{L}$-submodule of $o_{L} \llbracket Z \rrbracket$. For brevity, we will write

$$
A:=S \llbracket Z \rrbracket
$$

in this subsection. The $\psi_{q}$-operator is only defined on $A_{L}$ and it does not preserve $A$, in general.
Definition 3.4.1. Let $A^{\psi_{q} \text {-int }}$ be the largest $S$-submodule of $A$ stable under $\psi_{q}$.
Remark 3.4.2. We have $A^{\psi_{q}-\text { int }}=\left\{F \in A: \psi_{q}^{n}(F) \in A\right.$ for all $\left.n \geq 0\right\}$.
Lemma 3.4.3. The image of $\mathcal{K}^{*}: \mathcal{C}^{*} \rightarrow A$ is contained in $A^{\psi_{q}-\mathrm{int}}$.
Proof. Let $\lambda \in \mathcal{C}^{*}$. By Corollary 3.3.7, $\psi_{q}^{n}\left(\mathcal{K}^{*}(\lambda)\right)=\mathcal{K}^{*}\left(\left(\psi_{\mathcal{C}}^{*}\right)^{n}(\lambda)\right)$ lies in $A$ for all $n \geq 0$. Now use Remark 3.4.2.

Clearly, $A^{\psi_{q}=0}$ is contained in $A^{\psi_{q} \text {-int }}$; moreover this last is $\varphi$-stable in view of Remark 3.4.2 and the fact that $\psi_{q} \circ \varphi=1_{A}$ by Corollary 3.1.4. Therefore

$$
S+\sum_{n=0}^{\infty} \varphi^{n}\left(A^{\psi_{q}=0}\right) \subseteq A^{\psi_{q}-\mathrm{int}}
$$

Our next result makes this relation more precise; first we need some more notation.

Definition 3.4.4. We have the following truncation operators:
(1) $s: \mathcal{C} \rightarrow \mathcal{C}$, given by $s(f)=f-f(0) 1$, and
(2) $t: A \rightarrow A$, given by $t(a)=a-a(0) 1$.

It will be helpful to observe that $t \varphi=\varphi t$ as $S$-linear endomorphisms of $A$.
Proposition 3.4.5. There is a well-defined $o_{L}$-linear bijection

$$
1 \oplus \sum_{n=0}^{\infty} \varphi^{n} t: o_{L} \oplus \prod_{n=0}^{\infty} A^{\psi_{q}=0} \xrightarrow{\cong} A^{\psi_{q}-\mathrm{int}}
$$

Proof. Given any $\left(a_{n}\right)_{n} \in \prod_{n=0}^{\infty} A^{\psi_{q}=0}$, Lemma 3.1.7 implies that $\varphi^{n}\left(t\left(a_{n}\right)\right) \rightarrow$ 0 as $n \rightarrow \infty$, because $t\left(a_{n}\right) \in Z A$ for all $n \geq 0$. Hence

$$
\left(z,\left(a_{n}\right)_{n}\right) \mapsto z+\sum_{n=0}^{\infty} \varphi^{n}\left(t\left(a_{n}\right)\right)
$$

is a well-defined $S$-linear map $\gamma: S \oplus \prod_{n=0}^{\infty} A^{\psi_{q}=0} \rightarrow A$. Now $A^{\psi_{q} \text {-int }}$ is a $t$-stable $S$-submodule of $A$ since $\psi_{q}(1)=1$. Because $a_{n} \in A^{\psi_{q}=0}$, this implies that $\varphi^{n}\left(t\left(a_{n}\right)\right)=t \varphi^{n}\left(a_{n}\right) \in t\left(A^{\psi_{q} \text {-int }}\right) \subseteq A^{\psi_{q} \text {-int }}$ for any $n \geq 0$. Since $\psi_{\text {Col }}: A \rightarrow A$ is continuous by Lemma 3.1.6 and since $A^{\psi_{q}-\mathrm{int}}=\left\{a \in A: \psi_{\text {Col }}^{n}(a) \in q^{n} A\right.$ for all $n \geq 0\}$ by Remark 3.4.2, we see that $A^{\psi_{q} \text {-int }}$ is a closed $S$-submodule of $A$ with respect to the $\langle\pi, Z\rangle$-adic topology on $A=S \llbracket Z \rrbracket$. Hence the image of $\gamma$ is contained in $A^{\psi_{q}-\text { int }}$, and it remains to show that $\gamma$ is bijective.

Suppose that $\gamma\left(z,\left(a_{n}\right)_{n}\right)=0$ so that $z=-\sum_{n=0}^{\infty} \varphi^{n}\left(t\left(a_{n}\right)\right)$. Since $Z A$ is closed in $A$, this infinite sum lies in $Z A$. Since $S \cap Z A=0$, we conclude that $z=0$. Hence $a_{0}=-\sum_{n=1}^{\infty} \varphi^{n}\left(t\left(a_{n}\right)\right) \in \varphi(A)$. But $a_{0} \in A^{\psi_{q}=0}$ by definition, and

$$
A^{\psi_{q}=0} \cap \varphi(A)=0
$$

because $\psi_{q} \circ \varphi=1_{A}$ by Corollary 3.1.4. Hence $a_{0}=0$. Proceeding inductively on $n$, we quickly deduce that $a_{n}=0$ for all $n \geq 0$ in a similar manner. Hence $\gamma$ is injective.

Now let $a \in A^{\psi_{q} \text {-int }}$; then by definition, $\psi_{q}^{n}(a) \in A$ for all $n \geq 0$, so we can define

$$
a_{n}:=\psi_{q}^{n}(a)-\varphi \psi_{q}^{n+1}(a) \in A
$$

Since $\psi_{q} \circ \varphi=1_{A}$ by Corollary 3.1.4, we see that $a_{n} \in A^{\psi_{q}=0}$ for all $n \geq 0$. Since $t \varphi=\varphi t$,

$$
\sum_{n=0}^{m} \varphi^{n}\left(t\left(a_{n}\right)\right)=t\left(\sum_{n=0}^{m} \varphi^{n}\left(\psi_{q}^{n}(a)-\varphi \psi_{q}^{n+1}(a)\right)\right)=t\left(a-\varphi^{m+1} \psi_{q}^{m+1}(a)\right)
$$

for any $m \geq 0$. Since $t \varphi^{m+1} \psi_{q}^{m+1}(a)=\varphi^{m+1}\left(t \psi_{q}^{m+1}(a)\right) \rightarrow 0$ as $m \rightarrow \infty$ by Lemma 3.1.7,

$$
\gamma\left(a(0),\left(a_{n}\right)_{n}\right)=a(0)+t(a)-\lim _{m \rightarrow 0} \varphi^{m+1}\left(t \psi_{q}^{m+1}(a)\right)=a
$$

Hence $\gamma$ is surjective.
Lemma 3.4.6. For each $n \geq 0$, there is a commutative diagram

Proof. To see that the square on the left commutes, we use Corollary 3.3.7:

$$
\varphi^{n} \mathcal{K}_{1}^{*}=\varphi^{n} \mathcal{K}^{*} \mathrm{ev}_{1}^{*}=\mathcal{K}^{*} \varphi_{\mathcal{C}}^{*} \mathrm{ev}_{1}^{*}=\mathcal{K}^{*}\left(\operatorname{ev}_{1} \varphi_{\mathcal{C}}\right)^{*}=\mathcal{K}^{*} \mathrm{ev}_{\pi^{n}}^{*}
$$

Hence in view of Lemma 3.2.8(4), it remains to show that

$$
\left\langle u_{m}, \mathcal{K}^{*}\left(s^{*}(\lambda)\right)\right\rangle=\left\langle u_{m}, t\left(\mathcal{K}_{1}^{*}(\lambda)\right)\right\rangle \quad \text { for all } \quad m \geq 0, \lambda \in \mathcal{C}^{*}
$$

Since $t$ kills the constant term of a power series in $A$, we have

$$
\left\langle u_{m}, t(a)\right\rangle=\delta_{m \geq 1}\left\langle u_{m}, a\right\rangle \quad \text { for all } \quad a \in A .
$$

Now $\mathcal{K}\left(u_{m}\right)(0)=P_{m}(0)=\delta_{m, 0}$ by [28, Lemma 4.2] and $\mathcal{K}\left(u_{0}\right)=\mathcal{K}(1)=1$, so

$$
\begin{aligned}
& \left\langle u_{m}, \mathcal{K}^{*}\left(s^{*}(\lambda)\right)\right\rangle=\lambda\left(s\left(\mathcal{K}\left(u_{m}\right)\right)\right. \\
& \quad=\lambda\left(\mathcal{K}\left(u_{m}\right)-\mathcal{K}\left(u_{m}\right)(0) 1\right)=\delta_{m \geq 1} \lambda\left(\mathcal{K}\left(u_{m}\right)\right)=\left\langle u_{m}, t\left(\mathcal{K}^{*}(\lambda)\right)\right\rangle .
\end{aligned}
$$

The result follows.
Let $c_{0}\left(o_{\infty}\right):=\left\{\left(x_{n}\right)_{n} \in \prod_{n=0}^{\infty} o_{\infty}: \lim _{n \rightarrow \infty} x_{n}=0\right\}$.
Lemma 3.4.7. Suppose that $\tau$ is surjective. Then the map

$$
\eta: \mathcal{C} \rightarrow o_{L} \oplus c_{0}\left(o_{\infty}\right)
$$

given by $\eta(f)=\left(f(0),\left(f\left(\pi^{n}\right)-f(0)\right)_{n}\right)$ is an o o-linear bijection.
Proof. Recall that any $f \in \mathcal{C}$ takes values in $o_{\infty}$ by Lemma 3.3.2. Since $\pi^{n} \rightarrow 0$ as $n \rightarrow \infty$ in $o_{L}$ and since $f$ is continuous, $f\left(\pi^{n}\right)-f(0) \rightarrow 0$ as $n \rightarrow \infty$ in $o_{\infty}$. Thus $\eta$ is well-defined.

Suppose $\eta(f)=0$ for some $f \in \mathcal{C}$. Then $f(0)=0$ and $f\left(\pi^{n}\right)=0$ for all $n \geq 0$. Hence $f\left(\pi^{n} \tau(\sigma)\right)=\sigma\left(f\left(\pi^{n}\right)\right)=0$ for all $\sigma \in G_{L}$, so $f$ also vanishes on $\pi^{n} \tau\left(G_{L}\right)$ for each $n \geq 0$. Since $\tau$ is surjective, $f$ vanishes on $\bigcup_{n=0}^{\infty} \pi^{n} o_{L}^{\times} \cup\{0\}=o_{L}$, so $f=0$. Hence $\eta$ is injective.

To show $\eta$ is surjective, let $\left(z,\left(z_{n}\right)_{n}\right) \in o_{L} \oplus c_{0}\left(o_{\infty}\right)$ and define $f: o_{L} \rightarrow o_{\infty}$ by setting $f(0)=z$ and $f\left(\pi^{n} \tau(\sigma)\right):=z+\sigma\left(z_{n}\right)$ for all $n \geq 0$ and all $\sigma \in G_{L}$. This makes sense because $\tau$ is surjective, and if $\tau(\sigma)=\tau\left(\sigma^{\prime}\right)$ for some $\sigma, \sigma^{\prime} \in$ $G_{L}$ then $\sigma^{-1} \sigma^{\prime} \in \operatorname{ker} \tau$ fixes $o_{\infty}$ by Lemma 2.7.2, so $\sigma^{\prime}\left(z_{n}\right)=\sigma\left(\sigma^{-1} \sigma^{\prime}\left(z_{n}\right)\right)=$ $\sigma\left(z_{n}\right)$ for any $n \geq 0$. It is easy to see that $f: o_{L} \rightarrow o_{\infty}$ is Gal-continuous and that $\eta(f)=\left(z,\left(z_{n}\right)_{n}\right)$. Hence $\eta$ is surjective.

Lemma 3.4.7 allows us to give an explicit description of the space of Galois measures $\mathcal{C}^{*}$.

Corollary 3.4.8. Suppose $\tau$ is surjective. Then

$$
\eta^{*}: o_{L} \oplus \prod_{n=0}^{\infty} o_{\infty}^{*} \rightarrow \mathcal{C}^{*}
$$

is an o $o_{L}$-linear bijection.
Proof. The functor $(-)^{*}=\operatorname{Hom}_{o_{L}}(-, S)$ from $o_{L}$-modules to $S$-modules commutes with finite direct sums and sends $c_{0}\left(o_{\infty}\right)$ to $\prod_{n=0}^{\infty} o_{\infty}^{*}$. Now apply this functor to the isomorphism $\eta: \mathcal{C} \xrightarrow{\cong} o_{L} \oplus c_{0}\left(o_{\infty}\right)$ from Lemma 3.4.7.
Theorem 3.4.9. Suppose that $\tau$ is surjective and that $\mathcal{K}_{1}^{*}: o_{\infty}^{*} \rightarrow A^{\psi_{q}=0}$ is an isomorphism. Then $\mathcal{K}^{*}: \mathcal{C}^{*} \rightarrow A^{\psi_{q}-\mathrm{int}}$ is an isomorphism as well.

Proof. Using Corollary 3.4.8 and Proposition 3.4.5, we can build the following diagram:

$$
\begin{aligned}
& S \oplus \prod_{n=0}^{\infty} o_{\infty}^{*} \xrightarrow[\eta^{*}]{ } \mathcal{C}^{*} \\
& 1 \oplus \prod_{n=0}^{\infty} \mathcal{K}_{1}^{*} \\
& \downarrow \\
& S \oplus \prod_{n=0}^{\infty} A^{\psi_{q}=0} \xrightarrow{1 \oplus \sum_{n=0}^{\infty} \varphi^{n} t}
\end{aligned}
$$

Note that we can write $\eta=\mathrm{ev}_{0} \oplus\left(\mathrm{ev}_{\pi^{n}} \circ s\right)_{n}$. Lemma 3.4.6 implies that

$$
\mathcal{K}^{*}\left(\mathrm{ev}_{\pi^{n}} \circ s\right)^{*}=\mathcal{K}^{*} s^{*} \mathrm{ev}_{\pi^{n}}^{*}=t \varphi^{n} \mathcal{K}_{1}^{*}=\varphi^{n} t \mathcal{K}_{1}^{*} \quad \text { for any } \quad n \geq 0
$$

Using $P_{m}(0)=\delta_{m, 0}$ again together with (6), we also have
$\mathcal{K}^{*}\left(\eta^{*}\left(1,(0)_{n}\right)\right)=\mathcal{K}^{*}\left(\operatorname{ev}_{0}^{*}(1)\right)=\sum_{m=0}^{\infty} \operatorname{ev}_{0}^{*}(1)\left(P_{m}(-\Omega)\right) Z^{m}=\sum_{m=0}^{\infty} P_{m}(0) Z^{m}=1$.
So the diagram is commutative. Now $\eta^{*}$ is an isomorphism by Corollary 3.4.8, and the bottom map is an isomorphism by Proposition 3.4.5. Since $\mathcal{K}_{1}^{*}$ is an isomorphism by assumption, the vertical map on the left is an isomorphism. Hence $\mathcal{K}^{*}$ is also an isomorphism by the commutativity of the diagram.

Corollary 3.4.10. Let $S$ be any $\pi$-adically complete $o_{L}$-algebra. The dual Katz map

$$
\mathcal{K}^{*}: \mathcal{C}^{*} \rightarrow S \llbracket Z \rrbracket^{\psi_{q}-\mathrm{int}}
$$

is an isomorphism if $\tau: G_{L} \rightarrow o_{L}^{\times}$and $\mathcal{K}_{1}: \widehat{U} \rightarrow o_{\infty}$ are surjective, and $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$ is injective.

Proof. Apply Theorem 3.4.9 together with Proposition 3.3.10.
Remark 3.4.11. Katz claims on [19, p. 60] that it is easy to show that the map that he denotes by $(* *)$ on p.59, is injective. In our notation, this map is $\mathcal{K}^{*}$; at least when $\tau$ is surjective, the proof of Theorem 3.4.9 shows that its injectivity is equivalent to the injectivity of $\mathcal{K}_{1}^{*}$, which is equivalent to $\mathcal{K}_{1}(\widehat{U}) \cdot L=L_{\infty}$ in view of the proof of Proposition 3.3.10. We were only able to establish the equality $\mathcal{K}_{1}(\widehat{U})=o_{\infty}$ in the case where $L=\mathbb{Q}_{p^{2}}$ by carrying out an explicit computation - see Proposition 3.6.5 below.
3.5. The Newton polygon of $\Delta_{1}(Z)-1$. In this section, we obtain some estimates on $v_{\pi}\left(P_{k}(\Omega)\right), k \geq 1$. Recall that $d$ and $e$ and $f$ denote the degree and ramification and inertia indices of $L / \mathbb{Q}_{p}$, respectively.

Lemma 3.5.1. If $k \geq 0$ and $1 \leq r \leq e$, then we have an isomorphism of abelian groups

$$
o_{L} / \pi^{e k+r} o_{L} \cong\left(\mathbb{Z} / p^{k} \mathbb{Z}\right)^{f(e-r)} \oplus\left(\mathbb{Z} / p^{k+1} \mathbb{Z}\right)^{f r}
$$

Proof. Note that $p o_{L}=\pi^{e} o_{L} \subseteq \pi^{r} o_{L}$ since $e \geq r$ by assumption, so $o_{L} / \pi^{r} o_{L}$ is an elementary abelian $p$-group of order $\left|o_{L} / \pi^{r} o_{L}\right|=p^{f r}$. Hence, using the elementary divisors theorem, we can find $v_{1}, \cdots, v_{d} \in o_{L}$ such that

$$
o_{L}=\mathbb{Z}_{p} v_{1} \oplus \cdots \oplus \mathbb{Z}_{p} v_{d} \quad \text { and } \quad \pi^{r} o_{L}=\bigoplus_{i=1}^{s} \mathbb{Z}_{p} v_{i} \oplus \bigoplus_{i=s+1}^{d} \mathbb{Z}_{p} p v_{i}
$$

for some integer $s$ with $1 \leq s \leq d$. We deduce that $f r=d-s$, so $s=f(e-r)$. Since $\pi^{e k+r} o_{L}=p^{k} \pi^{r} o_{L}$, the result now follows easily.
Lemma 3.5.2. In $o_{L} / \pi^{e k+r} o_{L}$, the image of 1 has order $p^{k+1}$.
Proof. This can be proved directly as $p^{k} \cdot 1 \in \pi^{e k} \cdot o_{L}^{\times} \neq 0$ in $o_{L} / \pi^{e k+r} o_{L}$.
Definition 3.5.3. Let $m \geq 0$.
(1) Let $k_{m}=\lfloor(m-1) / e\rfloor$, so that $m=e k_{m}+r$ with $1 \leq r \leq e$.
(2) Define $x_{m}:=q^{m} / p^{k_{m}+1}$.
(3) Define

$$
y_{0}=\frac{e}{p-1}-\frac{1}{q-1} \text { and } y_{m}=\frac{e}{p-1}-\sum_{j=1}^{m-1} \frac{1}{p^{k_{j}+1}}-\frac{q}{p^{k_{m}+1}(q-1)}
$$

For example, $x_{0}=1$ and $x_{1}=q / p$. Note that if $m=e n+r$ with $1 \leq r \leq e$, then

$$
y_{e n+r}=\frac{e}{p^{n}(p-1)}-\frac{r}{p^{n+1}}-\frac{1}{(q-1) p^{n+1}} .
$$

Theorem 3.5.4. The vertices of the Newton polygon of $\Delta_{1}(Z)-1$ (using the valuation $v_{\pi}$, and excluding the point $(0,+\infty)$ ) are the points $\left(x_{m}, y_{m}\right)$ for $m \geq 0$.

Proof. Via the Schneider-Teitelbaum isomorphism $\kappa: \mathbf{B}\left(\mathbb{C}_{p}\right) \xrightarrow{\cong} \mathfrak{X}\left(\mathbb{C}_{p}\right)$, the zeroes of the power series

$$
\Delta_{1}(Z)-1=\sum_{m=1}^{\infty} P_{m}(\Omega) Z^{m} \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket
$$

are the $z \in \mathfrak{m}_{\mathbb{C}_{p}}$ such that $\kappa(z)$ is an $L$-analytic character satisfying $\kappa(z)(1)=1$. These characters are torsion ${ }^{3}$, and correspond to some of the torsion points of the Lubin-Tate group $\mathcal{G}$. There are precisely $q^{m}$ points in $\mathcal{G}\left[\pi^{m}\right]$, and the common valuation of each point $z \in \mathcal{G}\left[\pi^{m}\right] \backslash \mathcal{G}\left[\pi^{m-1}\right]$ is $v_{\pi}(z)=1 / q^{m-1}(q-1)$.

If we write $m=e k+r$ as above, then in view of Lemma 3.5.1 and Lemma 3.5.2 there are $x_{m}=q^{m} / p^{k_{m}+1}$ elements $z \in \mathcal{G}\left[\pi^{m}\right]$ such that $\kappa(z)(1)=1$.

Let $\left(\left(x_{m}^{\prime}, y_{m}^{\prime}\right)\right)_{m=0}^{\infty}$ be the vertices of the Newton polygon, so that the first vertex is $\left(x_{0}^{\prime}, y_{0}^{\prime}\right)=\left(1, v_{\pi}(\Omega)\right)=\left(x_{0}, y_{0}\right)$. The slope of the line segment between $\left(x_{m-1}^{\prime}, y_{m-1}^{\prime}\right)$ and $\left(x_{m}^{\prime}, y_{m}^{\prime}\right)$ is minus the common valuation of the elements of

[^1]$z \in \mathcal{G}\left[\pi^{m}\right] \backslash \mathcal{G}\left[\pi^{m-1}\right]$ satisfying $\kappa(z)=1$, that is $1 / q^{m-1}(q-1)$. Hence $x_{m}^{\prime}=x_{m}$ for all $m \geq 0$. Using the definitions of $x_{m}$ and $y_{m}$, we have the formula
$$
y_{m}=y_{0}-\frac{x_{1}-x_{0}}{q^{1-1}(q-1)}-\cdots-\frac{x_{m}-x_{m-1}}{q^{m-1}(q-1)}
$$
which implies that $y_{m}^{\prime}=y_{m}$ for all $m \geq 0$.
Remark 3.5.5. Note that $y_{m} \rightarrow 0$ as $m \rightarrow+\infty$. This is consistent with the fact that $\left\|\Delta_{1}(Z)-1\right\|=1$.
Corollary 3.5.6. We have the following formulas for $v_{\pi}\left(P_{k}(\Omega)\right)$.
(1) For all $m \geq 0$, we have $v_{\pi}\left(P_{x_{m}}(\Omega)\right)=y_{m}$.
(2) For all $n \geq 0$, we have $v_{\pi}\left(P_{p^{n(d-1)}}(\Omega)\right)=1 / p^{n} \cdot v_{\pi}(\Omega)$.

Proof. Item (1) follows immediately from Theorem 3.5.4. Item (2) follows from item (1) with $m=e n$. Indeed, $x_{e n}=q^{e n} / p^{n}=p^{n(d-1)}$ and

$$
y_{e n}=\frac{e}{p-1}-\frac{e}{p}-\frac{e}{p^{2}}-\cdots-\frac{e}{p^{n-1}}-\frac{e-1}{p^{n}}-\frac{q}{p^{n}(q-1)}=\frac{1}{p^{n}} \cdot\left(\frac{e}{p-1}-\frac{1}{q-1}\right)
$$

Remark 3.5.7. If $L / \mathbb{Q}_{p}$ is unramified, then item (2) of Corollary 3.5.6 gives all the valuations of the $P_{k}(\Omega)$ that can be computed using the Newton polygon. For $n \geq 0$, we get

$$
\operatorname{val}_{p}\left(P_{p^{n(d-1)}}(\Omega)\right)=1 / p^{n} \cdot v_{\pi}(\Omega)=\frac{1}{p^{n-1}(p-1)} \cdot \frac{q / p-1}{q-1}
$$

Corollary 3.5.8. Suppose that $L=\mathbb{Q}_{p^{2}}$ and $\pi=p$. Then we have

$$
\operatorname{val}_{p}\left(P_{p^{k}}(\Omega)\right)=\frac{1}{p^{k-1}(q-1)} \quad \text { for all } \quad k \geq 1
$$

and if $k \geq 1$ and $p^{k-1} \leq m \leq p^{k}$, then

$$
\operatorname{val}_{p}\left(P_{m}(\Omega)\right) \geq \frac{1}{p^{k-1}(q-1)}+\frac{p^{k}-m}{q^{k-1}(q-1)}=\frac{1}{p^{k-2}(q-1)}-\frac{m-p^{k-1}}{q^{k-1}(q-1)}
$$

### 3.6. Verifying Conjecture 3.3 .11 in a special case.

Definition 3.6.1. Fix $m \geq 1$.
(1) Let $\mathcal{G}_{m}=\mathcal{G}\left[\pi^{m}\right]$ be the finite flat $o_{L}$-group scheme of $\pi^{m}$-torsion points in the Lubin-Tate formal group $\mathcal{G}$.
(2) Let $\mathcal{G}_{m}^{\prime}$ be the Cartier dual of $\mathcal{G}_{m}$.
(3) Let $U(m):=\mathcal{O}\left(\mathcal{G}_{m}^{\prime}\right)=\operatorname{Hom}_{o_{L}}\left(o_{L} \llbracket Z \rrbracket /\left\langle\varphi^{m}(Z)\right\rangle, o_{L}\right)$.
(4) Let $\mathcal{G}^{\prime}:=\operatorname{colim} \mathcal{G}_{m}^{\prime}$ be the dual $p$-divisible group to the $p$-divisible group defined by the formal group $\mathcal{G}$.
Recall that by Cartier duality - see [32, p. 177] - the period $\Omega \in \mathbb{C}_{p}$ corresponds to a choice of generator $t^{\prime} \in T_{p} \mathcal{G}^{\prime}=T_{\pi} \mathcal{G}^{\prime}$ as an $o_{L}$-module. We recall how this correspondence works. First, the element

$$
\Delta_{1}=\sum_{n=0}^{\infty} P_{n}(\Omega) Z^{n} \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket
$$

gives a compatible system of group-like elements $\left(\Delta_{1}(m)\right)_{m=1}^{\infty} \in \prod_{m=1}^{\infty} \mathcal{O}\left(\mathcal{G}_{m}\right)$, where $\Delta_{1}(m)$ is the image of $\Delta_{1}$ in $\mathcal{O}\left(\mathcal{G}_{m} \times_{o_{L}} o_{\mathbb{C}_{p}}\right)=o_{\mathbb{C}_{p}} \llbracket Z \rrbracket /\left\langle\varphi^{m}(Z)\right\rangle$ under the natural surjective homomorphism of $o_{\mathbb{C}_{p}}$-algebras $o_{\mathbb{C}_{p}} \llbracket Z \rrbracket \rightarrow \mathcal{O}\left(\mathcal{G}_{m} \times_{o_{L}} o_{\mathbb{C}_{p}}\right)$. Since $\mathcal{O}\left(\mathcal{G}_{m} \times o_{o_{L}} o_{\mathbb{C}_{p}}\right)$ can be identified with $\operatorname{Hom}_{o_{\mathbb{C}_{p}}}\left(\mathcal{O}\left(\mathcal{G}_{m}^{\prime} \times o_{o_{L}} o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right), \Delta_{1}(m)$ can be viewed as an $o_{\mathbb{C}_{p}}$-linear map $U(m) \otimes_{o_{L}} o_{\mathbb{C}_{p}} \rightarrow o_{\mathbb{C}_{p}}$ which is in fact an $o_{\mathbb{C}_{p}}-$ algebra homomorphism because $\Delta_{1}(m)$ is group-like. This map is determined by its restriction to $U(m)$; this restriction is an $o_{L}$-algebra homomorphism $t_{m}^{\prime}: U(m) \rightarrow o_{\mathbb{C}_{p}}$ and is therefore an element of $\mathcal{G}_{m}^{\prime}\left(\mathbb{C}_{p}\right)$.

Finally, the multiplication-by- $\pi$-maps $\mathcal{G}_{m+1}^{\prime}\left(\mathbb{C}_{p}\right) \rightarrow \mathcal{G}_{m}^{\prime}\left(\mathbb{C}_{p}\right)$ in the inverse system defining the Tate module $T_{\pi} \mathcal{G}^{\prime}$ are induced by the inclusions of $o_{L^{-}}$ algebras $U(m) \hookrightarrow U(m+1)$, so $t_{m+1 \mid U(m)}^{\prime}=t_{m}^{\prime}$ for all $m \geq 1$, and the generator $t^{\prime} \in T_{\pi} \mathcal{G}^{\prime}$ is given by $t^{\prime}=\left(t_{m}^{\prime}\right)_{m=1}^{\infty} \in \prod_{m=1}^{\infty} \mathcal{G}_{m}^{\prime}\left(\mathbb{C}_{p}\right)$.
Lemma 3.6.2. Let $m \geq 1$. The restriction of $\mathcal{K}_{1}$ to $U(m) \subset \widehat{U}$ is equal to $t_{m}^{\prime}$. Proof. Recall that we have identified $\widehat{U}$ with $o_{L} \llbracket Z \rrbracket_{\text {cts }}^{*}$ using Lemma 3.2.8(3). Let $u \in U(m)$ and let $\tilde{u} \in \widehat{U}$ be the corresponding $o_{L}$-linear map $o_{L} \llbracket Z \rrbracket \rightarrow o_{L}$ which kills $\left\langle\varphi^{m}(Z)\right\rangle$. Then

$$
t_{m}^{\prime}(u)=\Delta_{1}(m)(u)=\left\langle\tilde{u}, \Delta_{1}\right\rangle=\mathcal{K}(\tilde{u})(1)=\mathcal{K}_{1}(\tilde{u})
$$

and the result follows.
For each $m \geq 1$, let $L_{m}$ be the finite Galois extension of $L$ contained in $L_{\infty}=\mathbb{C}_{p}^{\mathrm{ker} \tau}$ defined by $\operatorname{Gal}\left(L_{\infty} / L_{m}\right)=\tau^{-1}\left(1+\pi^{m} o_{L}\right)$.

Lemma 3.6.3. Let $m \geq 1$. Then $t_{m}^{\prime}(U(m)) \subseteq o_{L_{m}}$.
Proof. Let $\sigma \in \operatorname{Gal}\left(L_{\infty} / L_{m}\right)$ so that $\tau(\sigma) \in 1+\pi^{m} o_{L}$. Then by definition of the character $\tau, \sigma$ acts trivially on $\mathcal{G}_{m}^{\prime}\left(\mathbb{C}_{p}\right)$. In other words, $\sigma\left(t_{m}^{\prime}(u)\right)=t_{m}^{\prime}(u)$ for all $u \in U(m)$ and hence $t_{m}^{\prime}(U(m)) \subseteq L_{\infty}^{\mathrm{Gal}\left(L_{\infty} / L_{m}\right)}=L_{m}$. But $U(m)$ is a finitely generated $o_{L}$-module so $t_{m}^{\prime}(U(m))$ is integral over $o_{L}$ and is therefore contained in $o_{L_{m}}$.

Recall from Definition 3.2.1(2) that $U=U(\mathcal{G})$ is the covariant bialgebra of the formal group $\mathcal{G}$.
Definition 3.6.4. For each $m \geq 1$, let $U(m)_{k}:=\operatorname{im}(U(m) \rightarrow \widehat{U} / \pi \widehat{U})$.
We will identify $U_{k}:=U / \pi U$ with $\widehat{U} / \pi \widehat{U}$ via the natural map $U / \pi U \rightarrow$ $\widehat{U} / \pi \widehat{U}$ and we regard $U(m)_{k}$ as being naturally embedded into $U(m+1)_{k}$.
Proposition 3.6.5. Suppose that $t_{m}^{\prime}(U(m))=o_{L_{m}}$ for all $m \geq 1$. Then $\mathcal{K}_{1}: \widehat{U} \rightarrow o_{\infty}$ is surjective.
Proof. Consider $o_{\tau}:=\bar{L} \cap o_{\infty}$. Since $o_{\tau}$ is $\pi$-adically dense in $o_{\infty}$, to prove that $\mathcal{K}_{1}(\widehat{U})$ contains $o_{\infty}$, it is enough to prove that it contains $o_{\tau}$. Fix $m \geq 1$. By Lemma 3.6.2, the restriction of $\mathcal{K}_{1}: \widehat{U} \rightarrow o_{\mathbb{C}_{p}}$ to $U(m)$ is equal to $t_{m}^{\prime}$.

Hence by assumption $o_{L_{m}}=t_{m}^{\prime}(U(m))=\mathcal{K}_{1}(U(m))$, so $o_{\tau}=\bigcup_{m \geq 1} o_{L_{m}}$ is also contained in $\mathcal{K}_{1}(\widehat{U})$.

Lemma 3.6.6. For each $m \geq 1$, we have $U(m)+\pi \widehat{U}=\sum_{r=0}^{q^{m}-1} o_{L} u_{r}+\pi \widehat{U}$.
Proof. Let $u \in U(m)$ and let $\tilde{u}: o_{L} \llbracket Z \rrbracket \rightarrow o_{L}$ be the corresponding $o_{L}$-linear form which vanishes on $\left\langle\varphi^{m}(Z)\right\rangle$. Consider $v:=\tilde{u}-\sum_{r=0}^{q^{m}-1} \tilde{u}\left(Z^{r}\right) u_{r} \in \widehat{U}$. For each $r<q^{m}, u_{r}$ sends $\left\langle\varphi^{m}(Z)\right\rangle$ into $\pi o_{L}$ because $\varphi^{m}(Z) \equiv Z^{q^{m}} \bmod \pi o_{L} \llbracket Z \rrbracket$. Since $\tilde{u}$ kills $\left\langle\varphi^{m}(Z)\right\rangle$, we see that $v$ also sends $\left\langle\varphi^{m}(Z)\right\rangle$ into $\pi o_{L}$. By construction, $v$ is zero on $1, Z, \cdots, Z^{q^{m}-1}$. Since

$$
\begin{equation*}
o_{L} 1 \oplus o_{L} Z \oplus \cdots \oplus o_{L} Z^{q^{m}-1} \oplus\left\langle\varphi^{m}(Z)\right\rangle=o_{L} \llbracket Z \rrbracket \tag{7}
\end{equation*}
$$

we conclude that $v\left(o_{L} \llbracket Z \rrbracket\right) \subseteq \pi o_{L}$ and hence $v=\pi w$ for some $o_{L}$-linear form $w: o_{L} \llbracket Z \rrbracket \rightarrow o_{L}$. Since $v: o_{L} \llbracket Z \rrbracket \rightarrow o_{L}$ is continuous for the weak topology on $o_{L} \llbracket Z \rrbracket$, so is $w$. Hence $w \in \widehat{U}$ and hence $\tilde{u} \in \sum_{r=0}^{q^{m}-1} o_{L} u_{r}+\pi \widehat{U}$. This shows that $\subseteq$ holds.

For the reverse containment, it is enough to show that $u_{r} \in U(m)+\pi \widehat{U}$ for each $r=0, \ldots, q^{m}-1$. Using (7), define an $o_{L}$-linear form $w_{r}: o_{L} \llbracket Z \rrbracket \rightarrow o_{L}$ which is zero on $\left\langle\varphi^{m}(Z)\right\rangle$ and which sends $Z^{i}$ to $\delta_{i, r}$ for each $0 \leq i<q^{m}$. Since $u_{r}$ sends $\left\langle\varphi^{m}(Z)\right\rangle$ into $\pi o_{L}$, the same is true of $u_{r}-w_{r}$. Since $u_{r}-w_{r}$ is zero on $1, Z, \cdots, Z^{q^{m}-1}$ by construction, we see that $u_{r}-w_{r}$ sends all of $o_{L} \llbracket Z \rrbracket$ into $\pi o_{L}$. Hence $u_{r}-w_{r}=\pi v_{r}$ for some $o_{L}$-linear form $v_{r}: o_{L} \llbracket Z \rrbracket \rightarrow o_{L}$. Since $u_{r}-w_{r}$ is continuous for the weak topology on $o_{L} \llbracket Z \rrbracket$, so is $v_{r}$. Because $w_{r}$ is zero on $\left\langle\varphi^{m}(Z)\right\rangle$, it lies in $U(m)$ and hence $u_{r}=w_{r}+\pi v_{r} \in U(m)+\pi \widehat{U}$.

Proposition 3.6.7. If $L=\mathbb{Q}_{p^{2}}$, then $t_{m}^{\prime}(U(m))=o_{L_{m}}$ for all $m \geq 1$.
Proof. Fix $m \geq 1$. By Lemma 3.6.6, for each $0 \leq r<q^{m}$ we can find $w_{r} \in$ $U(m)$ such that $w_{r}-u_{r} \in \pi \widehat{U}$. Set $r:=p^{2 m-1}=p q^{m-1}<q^{m}$. Note that $\mathcal{K}_{1}\left(u_{r}\right)=\mathcal{K}\left(u_{r}\right)(1)=\left\langle u_{r}, \Delta_{1}\right\rangle=P_{r}(\Omega)$. Since $L=\mathbb{Q}_{p^{2}}$, Corollary 3.5.8 applied with $k=2 m-1$ tells us that
$\operatorname{val}_{p}\left(\mathcal{K}_{1}\left(u_{r}\right)\right)=\operatorname{val}_{p}\left(P_{r}(\Omega)\right)=\frac{1}{p^{2 m-2}(q-1)}=\frac{1}{q^{m-1}(q-1)}=\left[L_{m}: L\right]^{-1}<1$.
Now $\pi o_{L}=p o_{L}$ since $L=\mathbb{Q}_{p^{2}}$, so $\mathcal{K}_{1}\left(u_{r}-w_{r}\right) \in \mathcal{K}_{1}(\pi \widehat{U}) \subseteq p o_{\mathbb{C}_{p}}$ since $\mathcal{K}_{1}$ takes values in $o_{\mathbb{C}_{p}}$. Hence $\operatorname{val}_{p}\left(\mathcal{K}_{1}\left(u_{r}\right)-\mathcal{K}_{1}\left(w_{r}\right)\right) \geq 1$ and $\operatorname{val}_{p}\left(\mathcal{K}_{1}\left(w_{r}\right)\right)=$ $\operatorname{val}_{p}\left(\mathcal{K}_{1}\left(u_{r}\right)\right)=\left[L_{m}: L\right]^{-1}$. Therefore $\mathcal{K}_{1}\left(w_{r}\right)$ is a uniformiser in $L_{m}$ and the result follows.

Now we start to explore the injectivity of $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$.
Lemma 3.6.8. For each $m \geq 1$, we have $U(m) \cap \pi \widehat{U}=\pi U(m)$.

Proof. Let $g=\pi h \in U(m)$ for some $h \in \widehat{U}$. Then $\pi\langle h, F\rangle=\langle\pi h, F\rangle=0$ for any $F \in\left\langle\varphi^{m}(Z)\right\rangle$. Hence $\langle h, F\rangle=0$ for all such $F$ as well, so $h \in U(m)$ and $g \in \pi U(m)$.

Corollary 3.6.9. The map $\mathcal{O}\left(\mathcal{G}_{m}^{\prime} \times_{o_{L}} k\right)=U(m) / \pi U(m) \rightarrow U(m)_{k}$ is an isomorphism.

Since $\mathcal{G}^{\prime}$ forms a $p$-divisible group, we have a closed immersion $\mathcal{G}_{m}^{\prime} \rightarrow \mathcal{G}_{m+1}^{\prime}$ for each $m \geq 1$. The comorphism of this map $\mathcal{O}\left(\mathcal{G}_{m+1}^{\prime}\right) \rightarrow \mathcal{O}\left(\mathcal{G}_{m}^{\prime}\right)$ is the dual of the $o_{L}$-Hopf algebra map $\mathcal{O}\left(\mathcal{G}_{m}\right) \rightarrow \mathcal{O}\left(\mathcal{G}_{m+1}\right)$ induced by $\varphi: \mathcal{O}(\mathcal{G}) \rightarrow \mathcal{O}(\mathcal{G})$. Using Corollary 3.6.9, we obtain connecting maps $\varphi_{k}^{*}: U(m+1)_{k} \rightarrow U(m)_{k}$.

Lemma 3.6.10. The comorphisms $\varphi_{k}^{*}: U(m+1)_{k} \rightarrow U(m)_{k}$ are surjective for all $m \geq 1$.

Proof. By Corollary 3.6.9, $U(m)_{k}$ is isomorphic as a $k$-vector space to

$$
\mathcal{O}\left(\mathcal{G}_{m}^{\prime} \times_{o_{L}} k\right)=\operatorname{Hom}_{k}\left(\mathcal{O}\left(\mathcal{G}_{m} \times_{o_{L}} k\right), k\right)
$$

Since $\varphi(Z) \equiv Z^{q} \bmod \pi o_{L} \llbracket Z \rrbracket$, we have $\mathcal{O}\left(\mathcal{G}_{m} \times_{o_{L}} k\right)=k \llbracket Z \rrbracket /\left\langle Z^{q m}\right\rangle$ and the $k$-algebra homomorphism $\varphi_{k}: k \llbracket Z \rrbracket /\left\langle Z^{q m}\right\rangle \rightarrow k \llbracket Z \rrbracket /\left\langle Z^{q(m+1)}\right\rangle$ which sends $Z$ to $Z^{q}$ is injective. Hence the dual map

$$
\varphi_{k}^{*}: \operatorname{Hom}_{k}\left(k \llbracket Z \rrbracket /\left\langle Z^{q(m+1)}\right\rangle, k\right) \rightarrow \operatorname{Hom}_{k}\left(k \llbracket Z \rrbracket /\left\langle Z^{q m}\right\rangle, k\right)
$$

is surjective and the result follows.
Next we consider an ideal $I$ of $U_{k}$ and we set $I(m):=I \cap U(m)$ for all $m \geq 1$. We assume that $I$ is $\varphi^{*}$-stable, in the sense that $\varphi^{*}(I) \subseteq I$.

Proposition 3.6.11. Suppose that $I$ is $a \varphi^{*}$-stable ideal of $U_{k}$ such that
 nite dimensional over $k$.

Proof. Let $m \geq 1$ and consider the short exact sequence

$$
0 \rightarrow I(m) \rightarrow U(m)_{k} \rightarrow U(m)_{k} / I(m) \rightarrow 0 .
$$

Since $I$ is $\varphi^{*}$-stable by assumption, we get a short exact sequence of towers of finite-dimensional $k$-vector spaces. Passing to the inverse limit therefore gives an exact sequence

$$
0 \rightarrow I(\infty):=\lim _{\hookleftarrow} I(m) \rightarrow \lim _{\hookleftarrow} U(m)_{k} \rightarrow \lim _{\leftarrow} \frac{U(m)_{k}}{I(m)} \rightarrow 0 .
$$

By assumption, the term on the right is a finite dimensional $k$-vector space. We see from Lemma 3.6.10 that the connecting maps $U(m+1)_{k} / I(m+1) \rightarrow$ $U(m)_{k} / I(m)$ induced by $\varphi^{*}$ are surjective. Therefore, for large $m$, all of these maps are necessarily isomorphisms, and hence there exists $m_{0} \geq 1$ such that

$$
\operatorname{dim} \frac{U(m+1)_{k}}{I(m+1)}=\operatorname{dim} \frac{U(m)_{k}}{I(m)} \quad \text { for all } \quad m \geq m_{0}
$$

Now the definition of $I(m)$ shows that the natural connecting maps in the opposite direction $U(m)_{k} / I(m) \rightarrow U(m+1)_{k} / I(m+1)$ is injective for any $m \geq 1$. So they are isomorphisms whenever $m \geq m_{0}$. The result follows.
Proposition 3.6.12. Let $J=\operatorname{ker} \mathcal{K}$ and let $I:=(J+\pi \widehat{U}) / \pi \widehat{U}$ be its image in $U_{k}$. Then $I$ is a $\varphi^{*}$-stable ideal in $U_{k}$ such that $\operatorname{dim} U_{k} / I=\infty$.
Proof. Since $\mathcal{K}$ is an $o_{L}$-algebra homomorphism by Lemma 3.3.5, $J$ is an ideal in $\widehat{U}$. Since $\mathcal{K} \varphi^{*}=\varphi_{\mathcal{C}} \mathcal{K}$ by Lemma 3.3.6, this ideal is in fact $\varphi^{*}$-stable. Hence its image $I$ in $U_{k}$ is also $\varphi^{*}$-stable.

Suppose that $h \in \widehat{U}$ and $r \geq 1$ are such that $\pi^{r} h \in J$. Then $\mathcal{K}\left(\pi^{r} h\right)=0$ in $\mathcal{C}$, so $\mathcal{K}(h)=0$ as well. So $J \cap \pi^{r} \widehat{U}=\pi^{r} J$ for all $r \geq 1$. Now consider the short exact sequence

$$
0 \rightarrow J \rightarrow \widehat{U} \rightarrow \mathcal{K}(U) \rightarrow 0
$$

Equip both $\widehat{U}$ and $\mathcal{K}(U)$ with the $\pi$-adic filtrations. Then the above shows that the subspace filtration on $J$ induced by the $\pi$-adic filtration on $\widehat{U}$ coincides with the $\pi$-adic filtration on $J$. Therefore we get a short exact sequence of gr $o_{L}$-modules

$$
0 \rightarrow \operatorname{gr} J \rightarrow \operatorname{gr} \widehat{U} \rightarrow \operatorname{gr} \mathcal{K}(U) \rightarrow 0
$$

So, if $\operatorname{dim} U_{k} / I<\infty$, then $\operatorname{gr} \widehat{U} / \operatorname{gr} J \cong\left(U_{k} / I\right)[\operatorname{gr} \pi]$ is a finitely generated module over gr $o_{L}$, so $\operatorname{gr} \mathcal{K}(U)$ is a finitely generated gr $o_{L}$-module. The $\pi$ adic filtration on $\mathcal{C}$ is separated, hence the $\pi$-adic filtration on $\mathcal{K}(U)$ is also separated. Therefore $\mathcal{K}(U)$ is a finitely generated $o_{L}$-module by [22, Chapter I, Theorem 5.7]. Hence $\operatorname{dim}_{L} \mathcal{K}(U[1 / \pi])<\infty$. But this contradicts [28, Theorem 4.7]: the space of locally $L$-analytic Gal-continuous functions is not finite dimensional over $L$ since it contains the subspace of locally constant Gal-continuous functions, which is infinite dimensional over $L$.

Corollary 3.6.13. If $d:=\left[L: \mathbb{Q}_{p}\right]=2$, then $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$ is injective.
Proof. By Proposition 3.6.12, $I=(\operatorname{ker} \mathcal{K}+\pi \widehat{U}) / \pi \widehat{U}$ is a $\varphi^{*}$-stable ideal in $U_{k}$ of infinite codimension in $U_{k}$. Hence $I(\infty):=\lim \left(I \cap U(m)_{k}\right)$ is an ideal of infinite codimension in $\lim U(m)_{k}$ by Proposition 3.6.11. By [18, Example 2.5.3], the Dieudonné module $M\left(\mathcal{G}_{k}\right)$ associated with the Lubin-Tate formal group $\mathcal{G}_{k}=\mathcal{G} \times_{o_{L}} k$ over the perfect field $k$ has basis $\left\{\gamma, V \gamma, \cdots, V^{d-1} \gamma\right\}$ over the ring of $p$-typical Witt vectors $\mathbb{W}(k)$ for a certain element $\gamma \in M\left(\mathcal{G}_{k}\right)$, and satisfies $V^{d}=p$. Hence the Verschiebung operator $V$ on $M\left(\mathcal{G}_{k}\right)$ is topologically nilpotent. Therefore the Cartier dual $\mathcal{G}_{k}^{\prime}$ is connected. Hence $\lim _{\leftrightarrows} U(m)_{k} \cong$ $\mathcal{O}\left(\mathcal{G}^{\prime} \times_{o_{L}} k\right)$ is isomorphic to $k \llbracket X_{1}, \cdots, X_{d-1} \rrbracket$ by [32, Propositions 1 and 3]. Since $d=2$, we conclude that $I(\infty)=0$. Hence $I(m)=0$ for all $m \geq 1$ and hence $I=0$. So $\operatorname{ker} \mathcal{K}=0$ as well.

Theorem 3.6.14. Suppose that $L=\mathbb{Q}_{p^{2}}$. Then

$$
\mathcal{K}_{1}^{*}: o_{\infty}^{*} \rightarrow o_{L} \llbracket Z \rrbracket^{\psi_{q}=0}
$$

is an o $o_{L}$-linear bijection.

Proof. Since $d=2$, we know that $\tau$ is surjective by Lemma 2.6.4. Then $\mathcal{K}: \widehat{U} \rightarrow \mathcal{C}$ is injective by Corollary 3.6 .13 and $\mathcal{K}_{1}: \widehat{U} \rightarrow o_{\infty}$ is surjective by Proposition 3.6.5 and Proposition 3.6.7. Now apply Proposition 3.3.10.

We can now prove Theorem 1.6.1 from the Introduction. In fact, we prove the following more general version, from which Theorem 1.6.1 follows as a special case by setting $S=o_{K}$.

Theorem 3.6.15. Let $L=\mathbb{Q}_{p^{2}}$ and let $S$ be a $\pi$-adically complete $o_{L}$-algebra.
(1) The map $\mathcal{K}^{*}: \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), S\right) \rightarrow S \llbracket Z \rrbracket$ is injective.
(2) Its image is equal to $S \llbracket Z \rrbracket^{\psi_{q}-\mathrm{int}}$.

Proof. Since $d=2, \tau$ is surjective by Lemma 2.6.4. By Theorem 3.6.14, the $\operatorname{map} \mathcal{K}_{1}^{*}: o_{\infty}^{*} \rightarrow o_{L} \llbracket Z \rrbracket^{\psi_{q}=0}$ is an isomorphism. Now apply Theorem 3.4.9.

## 4. INTEGER-VALUED POLYNOMIALS

4.1. The algebraic dual of $\mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)$. Recall from $\S 2.1$ that our coefficient field $K$ is a complete field extension of $L$ contained in $\mathbb{C}_{p}$. Pick a basis $\left\{v_{1}, \cdots, v_{d}\right\}$ for $o_{L}$ as a $\mathbb{Z}_{p}$-module with $v_{1}=1$. We view $o_{L}$ as a $p$-valued group with $p$-valuation $\omega$ given by

$$
\omega\left(\sum_{i=1}^{d} \lambda_{i} v_{i}\right)=1+\min _{1 \leq i \leq d} \operatorname{val}_{p}\left(\lambda_{i}\right)
$$

Let $r$ be a real number in the range $1 / p \leq r<1$. Recall from [29, §4] that $D^{\mathbb{Q}_{p}-\mathrm{an}}\left(o_{L}, K\right)$ carries a norm $\|\cdot\|_{r}$ given by

$$
\begin{equation*}
\left\|\sum_{\alpha \in \mathbb{N}^{d}} d_{\alpha} \mathbf{b}^{\alpha}\right\|_{r}=\sup _{\alpha \in \mathbb{N}^{d}}\left|d_{\alpha}\right| r^{|\alpha|} . \tag{8}
\end{equation*}
$$

where $b_{i}:=\delta_{v_{i}}-1 \in D^{\mathbb{Q}_{p}-\text { an }}\left(o_{L}, K\right)$ for $i=1, \cdots, d, \mathbf{b}^{\alpha}=b_{1}^{\alpha_{1}} \cdots b_{d}^{\alpha_{d}} \in$ $D^{\mathbb{Q}_{p}-\mathrm{an}}\left(o_{L}, K\right)$ and $|\alpha|=\tau \alpha=\alpha_{1}+\cdots+\alpha_{d}$ for all $\alpha \in \mathbb{N}^{d}$.

Definition 4.1.1. Let $1 / p \leq r<1$.
(1) Let $D_{r}^{\mathbb{Q}_{p}-\mathrm{an}}\left(o_{L}, K\right)$ denote the completion of $D^{\mathbb{Q}_{p}-\mathrm{an}}\left(o_{L}, K\right)$ with respect to $\|\cdot\|_{r}$.
(2) Let $\mathfrak{X}_{0}(r)_{K}:=\operatorname{Sp} D_{r}^{\mathbb{Q}_{p}-\mathrm{an}}\left(o_{L}, K\right)$.
(3) Let $\mathfrak{X}(r)_{K}:=\mathfrak{X}_{K} \cap \mathfrak{X}_{0}(r)_{K}=\operatorname{Sp} D_{r}^{L-\text { an }}\left(o_{L}, K\right)$, where $D_{r}^{L-\text { an }}\left(o_{L}, K\right)$ is the factor algebra of $D_{r}^{\mathbb{Q}_{p}-\text { an }}\left(o_{L}, K\right)$ by the ideal generated by

$$
u_{2}-v_{2} u_{1}, \quad u_{3}-v_{3} u_{1}, \quad \cdots \quad, u_{d}-v_{d} u_{1}
$$

where $u_{i}:=\log \left(1+b_{i}\right) \in D^{\mathbb{Q}_{p}-\mathrm{an}}\left(o_{L}, K\right)$.
As $r$ approaches 1 from below, the $K$-affinoid varieties $\mathfrak{X}(r)_{K}$ form an increasing family of $K$-affinoid subvarieties of $\mathfrak{X}_{K}$ : whenever $1 / p \leq r<r^{\prime}<1$ we have

$$
\begin{equation*}
\mathbb{1} \in \mathfrak{X}(1 / p)_{K} \subset \cdots \subset \mathfrak{X}(r)_{K} \subset \mathfrak{X}\left(r^{\prime}\right)_{K} \subset \cdots \subset \mathfrak{X}_{K}=\bigcup_{1 / p \leq r<1} \mathfrak{X}(r)_{K} \tag{9}
\end{equation*}
$$

Here $\mathbb{1} \in \mathfrak{X}_{K}$ is the trivial character: the ideal generated by $b_{1}, \cdots, b_{d}$.
Lemma 4.1.2. The completed local ring $\widehat{\mathcal{O}_{\mathfrak{X}_{K}, \mathbb{1}}}$ of $\mathfrak{X}$ at $\mathbb{1}$ is isomorphic to a power series ring in one variable $b:=b_{1}$ over $K$ :

$$
\widehat{\mathcal{O}_{\mathfrak{X}, \mathbb{1}}} \cong K \llbracket b \rrbracket .
$$

Proof. We have $\mathcal{O}\left(\mathfrak{X}_{0}(1 / p)_{K}\right)=K\left\langle b_{1} / p, \cdots, b_{d} / p\right\rangle=K\left\langle u_{1} / p, \cdots, u_{d} / p\right\rangle$.
Quotienting out by the ideal generated by the elements $u_{i}-v_{i} u_{1}$ shows that $\mathcal{O}\left(\mathfrak{X}(1 / p)_{K}\right)=K\left\langle u_{1} / p\right\rangle=K\langle b / p\rangle$. So $\mathfrak{X}(1 / p)_{K}$ is isomorphic to the closed disc of radius $|p|=1 / p$ with local coordinate $b$; it is well known that the completed local ring at $b=0$ of such a disc is $K \llbracket b \rrbracket$. The result follows since $\mathbb{1} \in \mathfrak{X}(1 / p)_{K}$ implies that $\widehat{\mathcal{O}_{\mathfrak{X}_{K}, \mathbb{1}}}=\widehat{\mathcal{O}_{\mathfrak{X}(1 / p)_{K}, \mathbb{1}}}=K \llbracket b \rrbracket$.

Applying the functor $\mathcal{O}^{\circ}$ to the increasing chain of rigid $K$-varieties (9) and using Lemma 4.1.2 yields a decreasing chain of $o_{K}$-algebras

$$
\begin{align*}
K \llbracket b \rrbracket \supset \mathcal{O}^{\circ}\left(\mathfrak{X}(1 / p)_{K}\right) \supset \cdots & \supset \mathcal{O}^{\circ}\left(\mathfrak{X}(r)_{K}\right)  \tag{10}\\
& \supset \mathcal{O}^{\circ}\left(\mathfrak{X}\left(r^{\prime}\right)_{K}\right) \supset \cdots \supset \mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right) \supseteq o_{K} \llbracket o_{L} \rrbracket .
\end{align*}
$$

Definition 4.1.3. Let $A$ be an $o_{K}$-subalgebra of $K \llbracket b \rrbracket$ and let $m \geq 0$. The $m$-th infinitesimal neighbourhood of $\mathbb{1}$ in $A$ is the image $A_{m}$ of $A$ in $K \llbracket b \rrbracket / b^{m+1} K \llbracket b \rrbracket$ :

$$
A_{m}:=\frac{A+b^{m+1} K \llbracket b \rrbracket}{b^{m+1} K \llbracket b \rrbracket} \quad \subset \quad \frac{K \llbracket b \rrbracket}{b^{m+1} K \llbracket b \rrbracket} .
$$

Remark 4.1.4. This construction respects inclusions and is compatible with variation in $m$. More precisely, whenever $A \subseteq B$ are two $o_{K}$-subalgebras of $K \llbracket b \rrbracket$, for every $n \geq m$ there is a commutative diagram of $o_{K}$-algebras

with injective horizontal arrows and surjective vertical arrows.
Definition 4.1.5. Let $A$ be an $o_{K}$-subalgebra of $K \llbracket b \rrbracket$ and for each $m \geq 0$, let $A_{m}^{*}:=\operatorname{Hom}_{o_{K}}\left(A_{m}, o_{K}\right)$. The algebraic dual of $A$ is

$$
A_{\infty}^{*}:=\underset{m \geq 0}{\operatorname{colim}} A_{m}^{*}
$$

Lemma 4.1.6. Let $o_{K} \llbracket o_{L} \rrbracket \subseteq A \subseteq B$ be two o o $n \geq m \geq 0$.
(1) In the commutative square

all arrows are injective.
(2) The map $B_{\infty}^{*} \rightarrow A_{\infty}^{*}$ is injective.

Proof. (1) The vertical maps $A_{m}^{*} \rightarrow A_{n}^{*}$ are injective because $A_{n} \rightarrow A_{m}$ is surjective. Let $C$ be the cokernel of the map $A_{n} \rightarrow B_{n}$. Since $A_{n}$ contains $o_{K} \llbracket o_{L} \rrbracket_{n}$ which is an $o_{K}$-lattice in $K \llbracket b \rrbracket_{n}$, we see that $C$ is a torsion $o_{K}$-module. The dual functor $(-)^{*}$ is left exact, so we have the exact sequence $0 \rightarrow C^{*} \rightarrow$ $B_{n}^{*} \rightarrow A_{n}^{*}$. Since $C$ is torsion, $C^{*}=0$ which shows the injectivity of the horizontal arrows in our diagram.
(2) This follows by taking the colimit over all of the horizontal maps in part (1) above.

Thus we see that the connecting maps appearing in the colimit in Definition 4.1.5 are injective. Applying the contravariant algebraic dual functor $(-)_{\infty}^{*}$ to the chain (10) and using Lemma 4.1.6(2) gives us a chain of algebraic duals

$$
\begin{aligned}
& \mathcal{O}^{\circ}\left(\mathfrak{X}(1 / p)_{K}\right)_{\infty}^{*} \subset \cdots \subset \mathcal{O}^{\circ}\left(\mathfrak{X}(r)_{K}\right)_{\infty}^{*} \\
& \subset \mathcal{O}^{\circ}\left(\mathfrak{X}\left(r^{\prime}\right)_{K}\right)_{\infty}^{*} \subset \cdots \subset \mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)_{\infty}^{*} \subseteq o_{K} \llbracket o_{L} \rrbracket_{\infty}^{*} .
\end{aligned}
$$

We can now calculate the largest one of these, namely the algebraic dual of the Iwasawa algebra $o_{K} \llbracket o_{L} \rrbracket$, but first we must introduce integer-valued polynomials. Recall the following notion from [6].

Definition 4.1.7. A $\pi$-ordering for $o_{L}$ is a subset $\left\{\alpha_{0}, \alpha_{1}, \alpha_{2}, \ldots\right\}$ of $o_{L}$ such that

$$
\begin{equation*}
v_{\pi}\left(\prod_{i=0}^{k-1}\left(\alpha_{k}-\alpha_{i}\right)\right)=\inf _{s \in o} v_{\pi}\left(\prod_{i=0}^{k-1}\left(s-\alpha_{i}\right)\right) \quad \text { for all } \quad k \geq 1 \tag{11}
\end{equation*}
$$

Starting from an arbitrary element $\alpha_{0} \in o_{L}$, it is possible to construct a $\pi$-ordering $\left\{\alpha_{0}, \alpha_{1}, \ldots\right\}$ of $o_{L}$ by induction on $k$, choosing at each stage $\alpha_{k}$ to minimise the expression appearing on the right hand side of (11). In particular, $\pi$-orderings always exist, but are far from unique.

Definition 4.1.8. Let $\left\{\alpha_{0}, \alpha_{1}, \ldots\right\}$ be a $\pi$-ordering for $o_{L}$.
(1) Define the Lagrange polynomials as follows: $f_{0}(X):=1$ and
$f_{k}(X):=\frac{\left(X-\alpha_{0}\right)\left(X-\alpha_{1}\right) \cdots\left(X-\alpha_{k-1}\right)}{\left(\alpha_{k}-\alpha_{0}\right)\left(\alpha_{k}-\alpha_{1}\right) \cdots\left(\alpha_{k}-\alpha_{k-1}\right)} \in L[X]$ for each $k \geq 1$.
(2) Suppose that $R$ is an $o_{L}$-algebra which embeds into $R_{L}:=R \otimes_{o_{L}} L$. Then we define the ring of $R$-valued polynomials on $o_{L}$ as follows:

$$
\operatorname{Int}\left(o_{L}, R\right):=\left\{g(X) \in R_{L}[X]: g\left(o_{L}\right) \subset R\right\}
$$

(3) For each $m \geq 0$, let $\operatorname{Int}\left(o_{L}, R\right)_{m}$ denote the $R$-submodule of $\operatorname{Int}\left(o_{L}, R\right)$ consisting of all $R$-valued polynomials on $o_{L}$ of degree at most $m$.

The following result, closely related to de Shalit's work on Mahler bases [30], explains why we are interested in these Lagrange polynomials.

Lemma 4.1.9. The set $\left\{f_{0}, f_{1}, f_{2}, \ldots\right\}$ is an $R$-module basis for $\operatorname{Int}\left(o_{L}, R\right)$.

Proof. It follows directly from Definition 4.1.7 that $v_{\pi}\left(f_{k}(s)\right) \geq 0$ for all $s \in o_{L}$ and all $k \geq 0$. Hence $f_{k}\left(o_{L}\right) \subset o_{L} \subset R$ for all $k \geq 0$ which implies that

$$
\begin{equation*}
R f_{0}+R f_{1}+R f_{2}+\cdots+R f_{n}+\cdots \quad \subseteq \quad \operatorname{Int}\left(o_{L}, R\right) \tag{12}
\end{equation*}
$$

If $g \in R_{L}[X]$ has degree $n$ and leading coefficient $\lambda$, then $g-\lambda\left(\alpha_{n}-\alpha_{0}\right) \cdots\left(\alpha_{n}-\right.$ $\left.\alpha_{n-1}\right) f_{n}$ has degree strictly less than $n$. This implies that $\left\{f_{0}, f_{1}, f_{2}, \ldots\right\}$ generates $R_{L}[X]$ as an $R_{L}$-module. Now let $g \in \operatorname{Int}\left(o_{L}, R\right)$ and write $g=$ $\lambda_{0} f_{0}+\cdots+\lambda_{n} f_{n}$ for some $\lambda_{0}, \cdots, \lambda_{n} \in R_{L}$ as above. Setting $X=\alpha_{0}$ shows that $\lambda_{0}=g\left(\alpha_{0}\right) \in R$ since $g \in \operatorname{Int}\left(o_{L}, R\right)$. Assume inductively that $\lambda_{0}, \ldots, \lambda_{t-1} \in R$ for some $1 \leq t \leq n$. Setting $X=\alpha_{t}$ shows that

$$
\lambda_{t}=g\left(\alpha_{t}\right)-\lambda_{0} f_{0}\left(\alpha_{t}\right)-\lambda_{1} f_{1}\left(\alpha_{t}\right)-\cdots-\lambda_{t-1} f_{t-1}\left(\alpha_{t}\right)
$$

and this lies in $R$ because $g\left(\alpha_{t}\right) \in R$ and $f_{i}\left(\alpha_{t}\right) \in R$ for all $i$. This completes the induction and shows that we have equality in (12). Taking $g=0$ in the above argument also shows that the sum on the left hand side of (12) is direct.

Using Lemma 4.1.9, we obtain the following

## Corollary 4.1.10.

(1) The multiplication map

$$
\operatorname{Int}\left(o_{L}, o_{L}\right) \otimes_{o_{L}} o_{K} \rightarrow \operatorname{Int}\left(o_{L}, o_{K}\right)
$$

is an isomorphism, which sends $\operatorname{Int}\left(o_{L}, o_{L}\right)_{m} \otimes_{o_{L}} o_{K}$ onto $\operatorname{Int}\left(o_{L}, o_{K}\right)_{m}$ for any $m \geq 0$.
(2) The Lagrange polynomials $\left\{f_{0}(Y), \cdots, f_{m}(Y)\right\}$ associated with a choice of $\pi$-ordering for $o_{L}$ form an $o_{K}$-module basis for $\operatorname{Int}\left(o_{L}, o_{K}\right)_{m}$.
Proposition 4.1.11. The evaluation map ev : $\operatorname{Int}\left(o_{L}, o_{K}\right)_{m} \longrightarrow o_{K} \llbracket o_{L} \rrbracket_{m}^{*}$ defined by

$$
\operatorname{ev}(f(Y))(\lambda):=\lambda(f(Y))
$$

for all $f(Y) \in \operatorname{Int}\left(o_{L}, o_{K}\right)_{m}, \lambda \in o_{K} \llbracket o_{L} \rrbracket$ is an $o_{K}$-module isomorphism.
Proof. This is essentially a complicated-looking tautology, but we try to give the details.

Note that $o_{K} \llbracket o_{L} \rrbracket_{m}$ is an $o_{K}$-lattice in $K \llbracket b \rrbracket_{m}$. We can therefore identify $o_{K} \llbracket o_{L} \rrbracket_{m}^{*}$ with an $o_{K}$-submodule of $V:=\operatorname{Hom}_{K}\left(K \llbracket b \rrbracket_{m}, K\right)$, a $K$-vector space of dimension $m+1$. The linear functionals ev $(1), \mathrm{ev}(Y), \cdots, \mathrm{ev}\left(Y^{m}\right)$ are linearly independent in $V$ because if $\sum_{i=0}^{m} c_{i} \operatorname{ev}\left(Y^{i}\right)=0$ then $\operatorname{ev}\left(\sum_{i=0}^{m} c_{i} Y^{i}\right)\left(\delta_{a}\right)=$ $\sum_{i=0}^{m} c_{i} a^{i}=0$ for all $a \in o_{L}$ and this forces $c_{0}=\cdots=c_{m}=0$. It follows that ev : $K[Y]_{m} \rightarrow V$ is injective and is therefore an isomorphism by the ranknullity theorem.

Hence ev: $\operatorname{Int}\left(o_{L}, o_{K}\right)_{m} \rightarrow o_{K} \llbracket o_{L} \rrbracket_{m}^{*}$ is injective. However if $g \in o_{K} \llbracket o_{L} \rrbracket_{m}^{*}$ then by the above we can find some $f(Y) \in K[Y]_{m}$ such that $\operatorname{ev}(f(Y))=g$. Since $\delta_{a} \in o_{K} \llbracket o_{L} \rrbracket$ for all $a \in o_{L}$, we see that $f(a)=\operatorname{ev}(f(Y))\left(\delta_{a}\right)=g\left(\delta_{a}\right)$ must lie in $o_{K}$ for all $a \in o_{L}$.

Corollary 4.1.12. The map ev : $\operatorname{Int}\left(o_{L}, o_{K}\right) \rightarrow o_{K} \llbracket o_{L} \rrbracket_{\infty}^{*}$ is an isomorphism.

Proof. This follows immediately from Proposition 4.1.11.
Proposition 4.1.13. Suppose that $K$ is discretely valued. Then

$$
\mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)_{\infty}^{*}=\underset{r<1}{\operatorname{colim}} \mathcal{O}^{\circ}\left(\mathfrak{X}(r)_{K}\right)_{\infty}^{*}
$$

Proof. Since colimits commute with colimits, it is enough to show that for every $m \geq 0$,

$$
\mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)_{m}^{*}=\operatorname{colim}_{r<1} \mathcal{O}^{\circ}\left(\mathfrak{X}(r)_{K}\right)_{m}^{*}
$$

Fix $m \geq 0$. Then $\mathcal{O}^{\circ}\left(\mathfrak{X}(r)_{K}\right)_{m}$ form a decreasing chain of $o_{K}$-submodules of the $m+1$-dimensional $K$-vector space $K \llbracket b \rrbracket_{m}$, and all of them contain the $o_{K}$-lattice $o_{K} \llbracket o_{L} \rrbracket_{m}$. Since $K$ is discretely valued, the $o_{K}$-module $\left(K / o_{K}\right)^{m+1}$ satisfies the descending chain condition. Hence there exists $r_{0}<1$ such that

$$
\begin{equation*}
\mathcal{O}^{\circ}\left(\mathfrak{X}(r)_{K}\right)_{m}=\mathcal{O}^{\circ}\left(\mathfrak{X}\left(r_{0}\right)_{K}\right)_{m} \quad \text { whenever } \quad r_{0} \leq r<1 \tag{13}
\end{equation*}
$$

Following an argument of Schmidt [26, proof of Proposition 4.9], we will now show that

$$
\mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)_{m}=\mathcal{O}^{\circ}\left(\mathfrak{X}\left(r_{0}\right)_{K}\right)_{m} .
$$

The forward inclusion is clear, so fix some $\xi \in \mathcal{O}^{\circ}\left(\mathfrak{X}\left(r_{0}\right)_{K}\right)_{m}$, choose a sequence of real numbers $r_{0}<r_{1}<r_{2}<\cdots$ approaching 1 and consider the $K$-Banach space

$$
A_{j}:=\mathcal{O}\left(\mathfrak{X}\left(r_{j}\right)_{K}\right) .
$$

Let $\varphi_{j}: A_{j}^{\circ} \rightarrow K \llbracket b \rrbracket_{m}$ be the obvious $o_{K}$-linear map. Using (13) we see that the convex subset

$$
\varphi_{j}^{-1}(\xi) \subset A_{j}
$$

is non-empty. It was recorded in the proof of [29, Lemma 6.1] that the restriction maps $A_{j+1} \rightarrow A_{j}$ are compact. We may therefore argue as in [16, Proposition V.3.2] that

$$
\bigcap_{j=0}^{\infty} \varphi_{j}^{-1}(\xi) \subseteq \mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)
$$

is non-empty. Then any element $\lambda$ in this intersection satisfies $\lambda_{m}=\xi$, so $\xi \in$ $\mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)_{m}$ as required. Hence $\mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)_{m}^{*}=\mathcal{O}^{\circ}\left(\mathfrak{X}(r)_{K}\right)_{m}^{*}$ whenever $r_{0} \leq r<1$, and the result follows.
4.2. The matrix coefficients $\rho_{i, j}(Y)$. Let $\mathbf{B}_{\mathbb{C}_{p}}$ be the rigid analytic open unit disc of radius 1 defined over $\mathbb{C}_{p}$, with global coordinate function $Z$. There is a twisted $G_{L}=\operatorname{Gal}\left(\mathbb{C}_{p} / L\right)$-action on $\mathcal{O}\left(\mathbf{B}_{\mathbb{C}_{p}}\right)$ given by $F \mapsto F^{\sigma} \circ\left[\tau\left(\sigma^{-1}\right)\right]$, which induces an $L$-algebra isomorphism

$$
\mu: \mathcal{O}\left(\mathfrak{X}_{L}\right) \xrightarrow{\cong} \mathcal{O}\left(\mathbf{B}_{\mathbb{C}_{p}}\right)^{G_{L}, *}
$$

see [28, Corollary 3.8]. Inspecting the proof of this result, we see that it extends naturally to give a description of $\mathcal{O}\left(\mathfrak{X}_{K}\right)$ for more general closed coefficient fields $L \subseteq K \subseteq \mathbb{C}_{p}$ as well:

Lemma 4.2.1. There is a $K$-algebra isomorphism

$$
\mu_{K}: \mathcal{O}\left(\mathfrak{X}_{K}\right) \xrightarrow{\cong} \mathcal{O}\left(\mathbf{B}_{\mathbb{C}_{p}}\right)^{G_{K}, *} .
$$

Since $\mathcal{O}^{\circ}\left(\mathbf{B}_{\mathbb{C}_{p}}\right)=o_{\mathbb{C}_{p}} \llbracket Z \rrbracket$, we deduce the following
Corollary 4.2.2. There is an isomorphism of $o_{K}$-algebras

$$
\mu_{K}: \mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right) \xrightarrow{\cong} o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{G_{K}, *} .
$$

Until the end of $\S 4.2$, we assume that $\Omega$ is transcendental over $K$.
Definition 4.2.3. We call an $o_{K}$-subalgebra $R$ of $K[\Omega] \cap o_{\mathbb{C}_{p}}$ admissible if $P_{n}(\Omega) \in R$ for all $n \geq 0$, and if $R$ is stable under the natural $G_{L}$-action on $K[\Omega] \cap o_{\mathbb{C}_{p}}$ (in particular, $K$ itself is then stable under $G_{L}$ ).
Example 4.2.4. The algebra $K[\Omega] \cap o_{\mathbb{C}_{p}}$ is itself an admissible $o_{K}$-subalgebra of $K[\Omega]$.
Proof. This follows from Corollary 4.2.2 together with [28, Lemma 4.2(5)].
Definition 4.2.5. Let $R \subset K[\Omega]$ be an admissible $o_{K}$-subalgebra.
(1) Let $K[\Omega]_{n}:=\{f(\Omega) \in K[\Omega]: \operatorname{deg}(f) \leq n\}$ for each $n \geq 0$.
(2) Let $R_{n}:=R \cap K[\Omega]_{n}$ for each $n \geq 0$.
(3) $\left\{b_{n}(\Omega): n \geq 0\right\} \subset R$ is a regular basis if

$$
b_{0}(\Omega)=1, \quad \text { and } \quad R_{n}=R_{n-1} \oplus o_{K} b_{n}(\Omega) \quad \text { for all } \quad n \geq 1
$$

Lemma 4.2.6. Suppose that $K$ is discretely valued. Then a regular basis exists for every admissible $o_{K}$-subalgebra $R$ of $K[\Omega] \cap o_{\mathbb{C}_{p}}$.
Proof. Since $\Omega$ is assumed to be transcendental over $K$, the $K$-vector space $K[\Omega]_{n}$ has dimension $n+1$. The restriction of the norm $|\cdot|$ on $\mathbb{C}_{p}$ to $K[\Omega]_{n}$ turns it into a normed vector space over $K$ and by Definition 4.2.3(1), $R_{n}$ is contained in the unit ball with respect to this norm. Since any two norms on a finite dimensional $K$-vector space are equivalent - see [27, Proposition 4.13] - it follows that $R_{n} \subseteq \pi^{-m} o_{K}[\Omega]_{n}$ for sufficiently large $m$.

Since $K$ is discretely valued, its valuation ring $o_{K}$ is Noetherian and this forces $R_{n}$ to be a free $o_{K}$-module of rank $n+1$. Because the $R_{n}$ 's form a nested chain, we can now construct the desired $o_{K}$-module basis for $R$ by induction on $n$.

Example 4.2.7. Because $\Omega$ is assumed to be transcendental over $K$, Lemma 3.2.2(1) together with Lemma 3.2.3 implies that $\sum_{n=0}^{\infty} o_{K} P_{n}(\Omega)$ is isomorphic to $U(\mathcal{G}) \otimes_{o_{L}} o_{K}$ as an $o_{K}$-algebra. Abusing notation, we will write $U:=$ $\sum_{n=0}^{\infty} o_{K} P_{n}(\Omega)$ until the end of $\S 4$. Although this conflicts with Definition 3.2.1(2), we hope that no confusion will be caused by this abuse of notation. Then $U$ is an admissible subalgebra of $K[\Omega]$, and $\left\{P_{n}(\Omega): n \geq 0\right\}$ is a regular basis for $R$ : since $\operatorname{deg} P_{j}(Y)=j$, an element $f(\Omega)$ of $U_{n}$ is a $K$-linear combination of $P_{0}(\Omega), \cdots, P_{n}(\Omega)$ lying in $U$, but $\left\{P_{m}(\Omega): m \geq 0\right\}$ is an $o_{L}$-module basis for $U$ so all coefficients of $f(\Omega)$ must in fact lie in $o_{L}$.

Until the end of $\S 4.2$, we assume that

- $K$ is a discretely valued intermediate subfield $L \subseteq K \subseteq \mathbb{C}_{p}$,
- $\Omega$ is transcendental over $K$,
- $R \subseteq K[\Omega] \cap o_{\mathbb{C}_{p}}$ is an admissible $o_{K}$-subalgebra, and
- $\left\{b_{n}(\Omega): n \geq 0\right\}$ is a regular basis for $R$.

Lemma 4.2.8. Take $j \geq 0$.
(1) There are unique $\rho_{0, j}(Y), \rho_{1, j}(Y), \cdots, \rho_{j, j}(Y) \in K[Y]$ such that

$$
P_{j}(Y \Omega)=\sum_{i=0}^{j} \rho_{i, j}(Y) b_{i}(\Omega)
$$

(2) $\operatorname{deg} \rho_{i, j}(Y) \leq j$ whenever $0 \leq i \leq j$.
(3) $\operatorname{deg} \rho_{j, j}(Y)=j$.
(4) $\rho_{i, j}(a) \in o_{K}$ whenever $a \in o_{L}$ and $0 \leq i \leq j$.

Proof. (1) $\Omega$ is transcendental over $K$, and $\left\{b_{i}(\Omega): i \geq 0\right\}$ is a $K$-vector space basis for $K[\Omega]$ with $\operatorname{deg} b_{i}(\Omega)=i$ for each $i$. Hence it is also a $K[Y]$-module basis for the two-variable polynomial algebra $K[\Omega, Y]$, so we can find unique $\rho_{i, j}(Y) \in K[Y]$ such that

$$
P_{j}(Y \Omega)=\sum_{i \geq 0} \rho_{i, j}(Y) b_{i}(\Omega)
$$

where $\rho_{i, j}(Y)=0$ for sufficiently large $i$. Now $P_{j}(s)$ is a polynomial in $s$ of degree $j$ by $[28$, Lemma $4.2(3)]$, so $\Omega^{j}$ is the highest degree monomial in $\Omega$ appearing in $P_{j}(Y \Omega)$. Since $\operatorname{deg} b_{i}(\Omega)=i$, this means $\rho_{i, j}(Y)=0$ for $i>j$.
(2) Since the highest degree monomial in $Y$ appearing in $P_{j}(Y \Omega)$ is $Y^{j}$, this means that $\operatorname{deg} \rho_{i, j}(Y) \leq j$ for each $i \leq j$.
(3) The monomial $Y^{j} \Omega^{j}$ appears in $P_{j}(Y \Omega)$ with a non-zero coefficient. This monomial does not appear in $\rho_{i, j}(Y) b_{i}(\Omega)$ for any $i<j$ because $\operatorname{deg} b_{i}(\Omega)=i$ for all $i$. So it must appear in $\rho_{j, j}(Y) b_{j}(\Omega)$, and because of (2), this can only happen if $\operatorname{deg} \rho_{j, j}(Y)=j$.
(4) Let $a \in o_{L}$. We know that $P_{j}(a \Omega) \in o_{\mathbb{C}_{p}}$ by [28, Lemma 4.2(5)]; in fact, $P_{j}(a \Omega)$ is an $o_{L}$-linear combination of the $P_{i}(\Omega)$ for $0 \leq i \leq j$ by Corollary 3.2.6, so $P_{j}(a \Omega) \in R$. Setting $Y=a$ in (1) shows that $\rho_{i, j}(a) \in o_{K}$, since $\left\{b_{i}(\Omega): i \geq 0\right\}$ is a regular basis for $R$.

Theorem 4.2.9. For each $\lambda \in D^{L-\mathrm{an}}\left(o_{L}, K\right)$ we have

$$
\mu_{K}(\lambda)=\sum_{j=0}^{\infty} \sum_{k=0}^{j} \lambda\left(\rho_{k, j}(Y)\right) b_{k}(\Omega) Z^{j}
$$

In the case when $\lambda=\delta_{a}$ for some $a \in o_{L}$, Lemma 4.2.8 implies that

$$
\begin{aligned}
\mu\left(\delta_{a}\right)=\sum_{j=0}^{\infty} P_{j}(a \Omega) Z^{j}=\sum_{j=0}^{\infty}\left(\sum_{i=0}^{j} \rho_{i, j}(a) b_{i}(\Omega)\right) & Z^{j} \\
& =\sum_{j=0}^{\infty} \sum_{k=0}^{j} \delta_{a}\left(\rho_{k, j}(Y)\right) b_{k}(\Omega) Z^{j}
\end{aligned}
$$

which explains where the formula comes from. We will now give a rigorous argument to show that the formula is valid for any $\lambda \in D^{L-\text { an }}\left(o_{L}, K\right)$.

Lemma 4.2.10. Let $t:=\log _{L T}(Z)$ be the Lubin-Tate logarithm. Then

$$
\mu_{K}(\lambda)=\sum_{k=0}^{\infty} \lambda\left(Y^{k} / k!\right) \Omega^{k} t^{k} \quad \text { for all } \quad \lambda \in D^{L-\mathrm{an}}\left(o_{L}, K\right)
$$

Proof. We may identify $\mathbb{C}_{p} \llbracket t \rrbracket$ with $\mathbb{C}_{p} \llbracket Z \rrbracket$, and we write $\mu_{K}(\lambda)=\sum_{m=0}^{\infty} c_{i, m} t^{m}$ for some $c_{i, m} \in \mathbb{C}_{p}$. Then applying [28, Lemma 4.6(8)], we have

$$
\begin{aligned}
& \lambda\left(Y^{k} / k!\right)=\left\{\mu_{K}(\lambda), Y^{k} / k!\right\}=\frac{\left(\Omega^{-1} \partial_{t}\right)^{k}}{k!}\left(\mu_{K}(\lambda)\right)(0) \\
&=\Omega^{-k} c_{i, k} \quad \text { for all } \quad k \geq 0
\end{aligned}
$$

Proposition 4.2.11. Let $\lambda \in \operatorname{Hom}_{L}(L[Y], K)$. Then in $\mathbb{C}_{p} \llbracket t \rrbracket=\mathbb{C}_{p} \llbracket Z \rrbracket$,

$$
\sum_{k=0}^{\infty} \lambda\left(Y^{k} / k!\right) \Omega^{k} t^{k}=\sum_{j=0}^{\infty} \sum_{k=0}^{j} \lambda\left(\rho_{k, j}(Y)\right) b_{k}(\Omega) Z^{j}
$$

Proof. For each $k \geq 0$, write $t^{k}=\sum_{j=k}^{\infty} d_{j}^{(k)} Z^{j} \in L \llbracket Z \rrbracket$. Substituting this into Lemma 4.2.10 gives

$$
\begin{align*}
\sum_{k=0}^{\infty} \lambda\left(Y^{k} / k!\right) \Omega^{k} t^{k}=\sum_{k=0}^{\infty} \lambda\left(Y^{k} / k!\right) \Omega^{k} & \sum_{j=k}^{\infty} d_{j}^{(k)} Z^{j}  \tag{14}\\
& =\sum_{j=0}^{\infty}\left(\sum_{k=0}^{j} \frac{1}{k!} d_{j}^{(k)} \Omega^{k} \lambda\left(Y^{k}\right)\right) Z^{j}
\end{align*}
$$

On the other hand, the identity

$$
\sum_{j=0}^{\infty} P_{j}(Y \Omega) Z^{j}=\exp (Y \Omega t)=\sum_{k=0}^{\infty} \frac{1}{k!} t^{k} \Omega^{k} Y^{k}=\sum_{k=0}^{\infty} \frac{Y^{k} \Omega^{k}}{k!} \sum_{j=k}^{\infty} d_{j}^{(k)} Z^{j}
$$

together with Lemma 4.2 .8 shows that for all $j \geq 0$ we have

$$
\begin{equation*}
\sum_{k=0}^{j} \frac{1}{k!} d_{j}^{(k)} \Omega^{k} Y^{k}=P_{j}(\Omega Y)=\sum_{k=0}^{j} \rho_{k, j}(Y) b_{k}(\Omega) \tag{15}
\end{equation*}
$$

Now, the $L$-linear form $\lambda: L[Y] \rightarrow K$ extends to a $K[\Omega]$-linear form $K[\Omega, Y] \rightarrow$ $K[\Omega]$. Applying this extension to (15) gives

$$
\sum_{k=0}^{j} \frac{1}{k!} d_{j}^{(k)} \Omega^{k} \lambda\left(Y^{k}\right)=\sum_{k=0}^{j} \lambda\left(\rho_{k, j}(Y)\right) b_{k}(\Omega) .
$$

Substituting this equation into (14) gives the result.
Proof of Theorem 4.2.9. Follows immediately from Lemma 4.2.10 and Proposition 4.2.11.

Definition 4.2.12. Let $\check{R}$ be the $o_{K}$-linear span of $\left\{\rho_{k, j}(Y): j \geq k \geq 0\right\}$ in the space $I:=\operatorname{Int}\left(o_{L}, o_{K}\right)$ of $o_{K}$-valued polynomials on $o_{L}$.

We will see shortly that $\check{R}$ does not depend on the choice of regular basis for $R$.

Corollary 4.2.13. Let $\lambda \in D^{L-\mathrm{an}}\left(o_{L}, K\right)$. Then $\mu_{K}(\lambda) \in R \llbracket Z \rrbracket$ if and only if $\lambda(\check{R}) \subseteq o_{K}$.

Proof. Theorem 4.2.9 tells us that $\mu_{K}(\lambda)$ belongs to $R \llbracket Z \rrbracket$ if and only if $\sum_{k=0}^{j} \lambda\left(\rho_{k, j}(Y)\right) b_{k}(\Omega) \in R$ for all $j \geq 0$. Since $\left\{b_{k}(\Omega): k \geq 0\right\}$ is a regular basis, this is equivalent to $\lambda\left(\rho_{k, j}(Y)\right) \in o_{K}$ for all $j \geq k \geq 0$.

Proposition 4.2.14. Let $\lambda \in \operatorname{Hom}_{K}(K[Y], K)$ be such that $\lambda(\check{R}) \subseteq o_{K}$. Then there exists $\tilde{\lambda} \in \mu_{K}^{-1}(R \llbracket Z \rrbracket) \subseteq \mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)$ such that $\left.\tilde{\lambda}\right|_{K[Y]}=\lambda$.

Proof. The twisted $G_{L}$-action on $\mathbb{C}_{p} \llbracket Z \rrbracket$ preserves $R \llbracket Z \rrbracket$ since we assumed that $R \subseteq K[\Omega] \cap o_{\mathbb{C}_{p}}$ is $G_{L}$-stable in Definition 4.2.3. Therefore $R \llbracket Z \rrbracket^{G_{L}, *}$ makes sense.

Define $F_{\lambda}:=\sum_{j=0}^{\infty} \sum_{k=0}^{j} \lambda\left(\rho_{k, j}(Y)\right) b_{k}(\Omega) Z^{j} \in \mathbb{C}_{p} \llbracket Z \rrbracket$. Then $F_{\lambda} \in K \llbracket \Omega t \rrbracket=$ $\mathbb{C}_{p} \llbracket Z \rrbracket^{G_{K}, *}$ by Proposition 4.2.11 and $F_{\lambda} \in R \llbracket Z \rrbracket$ because $\lambda(\check{R}) \subseteq o_{K}$. Hence $F_{\lambda} \in R \llbracket Z \rrbracket^{G_{K}, *} \subseteq o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{G_{K}, *}$, so $F_{\lambda}=\mu_{K}(\tilde{\lambda})$ for some $\tilde{\lambda} \in \mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)$ by Corollary 4.2.2. In particular, $\tilde{\lambda} \in \mu_{K}^{-1}(R \llbracket Z \rrbracket)$.

Next, applying [28, Lemma 4.6(8)] we see that for all $m \geq 0$,

$$
\begin{aligned}
& \tilde{\lambda}\left(Y^{m} / m!\right)=\left\{\mu_{K}(\tilde{\lambda}), Y^{m} / m!\right\}=\left\{F_{\lambda}, Y^{m} / m!\right\} \\
&=\left\{\sum_{k=0}^{\infty} \lambda\left(Y^{k} / k!\right) \Omega^{k} t^{k}, Y^{m} / m!\right\}=\lambda\left(Y^{m} / m!\right) .
\end{aligned}
$$

Since the $Y^{m} / m$ ! span $K[Y]$ as a $K$-vector space, we have $\left.\tilde{\lambda}\right|_{K[Y]}=\lambda$.
Recall the isomorphism ev : $\operatorname{Int}\left(o_{L}, o_{K}\right) \rightarrow o_{K} \llbracket o_{L} \rrbracket_{\infty}^{*}$ from Corollary 4.1.12.
Theorem 4.2.15. We have $\operatorname{ev}(\check{R})=\mu_{K}^{-1}(R \llbracket Z \rrbracket)_{\infty}^{*}$.

Proof. The $o_{K}$-module $\check{R}$ contains the $o_{K}$-submodule of $K[Y]$ generated by $\left\{\rho_{j, j}(Y): j \geq 0\right\}$ and $\operatorname{deg} \rho_{j, j}(Y)=j$ for each $j \geq 0$ by Lemma 4.2.8(3). Hence $\check{R}$ spans $K[Y]$ as a $K$-vector space. On the other hand, $\check{R}_{n}:=\check{R} \cap K[Y]_{\leq n}$ is contained $\operatorname{in} \operatorname{Int}\left(o_{L}, o_{K}\right)_{n}$ by Lemma 4.2.8(4), which is a finitely generated $o_{K}$-module by Remark 4.1.10(2). Since $K$ is discretely valued, $\check{R}_{n}$ is a finitely generated $o_{K}$-module for each $n \geq 0$. So we can find an $o_{K}$-module basis $\left\{t_{0}, t_{1}, \cdots, t_{n}, \cdots\right\}$ for $\check{R}$ such that $\left\{t_{0}, \cdots, t_{n}\right\}$ is an $o_{K}$-module basis for $\check{R}_{n}$ for each $n \geq 0$. It follows that the natural map $\check{R} \otimes_{o_{K}} K \rightarrow K[Y]$ is an isomorphism, and we may identify $\operatorname{Hom}_{o_{K}}\left(\check{R}, o_{K}\right)$ with $\left\{\phi \in \operatorname{Hom}_{K}(\check{R}, K)\right.$ : $\left.\phi(\check{R}) \subseteq o_{K}\right\}$.

Let $\left\{t_{m}^{*}: m \geq 0\right\} \subset \operatorname{Hom}_{o_{K}}\left(\check{R}, o_{K}\right)$ be determined by

$$
t_{m}^{*}\left(t_{n}\right)=\delta_{m, n} \quad \text { for all } \quad m, n \geq 0
$$

Then by Proposition 4.2.14, $t_{m}^{*}$ extends to some $\lambda_{m} \in \mu_{K}^{-1}(R \llbracket Z \rrbracket)$ such that $\left.\lambda_{m}\right|_{K[Y]}=t_{m}^{*}$. In particular, we have $\lambda_{m}\left(t_{n}\right)=\delta_{m, n}$ for all $m, n \geq 0$.

Now suppose that $g \in \mu_{K}^{-1}(R \llbracket Z \rrbracket)_{\infty}^{*} \subseteq o_{K} \llbracket o_{L} \rrbracket_{\infty}^{*}$. Then $g=\operatorname{ev}(h)$ for some $h \in \operatorname{Int}\left(o_{L}, o_{K}\right)_{m}$ by Proposition 4.1.11. Since $h \in K[Y]_{\leq m}$ and since $\left\{t_{0}, \cdots, t_{m}\right\}$ is a $K$-vector space basis for $K[Y]_{m}$, we can write $h=\sum_{n=0}^{m} c_{n} t_{n}$ for some $c_{n} \in K$. But then

$$
g\left(\lambda_{n}\right)=\operatorname{ev}(h)\left(\lambda_{n}\right)=\lambda_{n}(h)=t_{n}^{*}(h)=c_{n} \quad \text { for all } \quad n \geq 0
$$

Since $\lambda_{n} \in \mu_{K}^{-1}(R \llbracket Z \rrbracket)$ and $g \in \mu_{K}^{-1}(R \llbracket Z \rrbracket)_{\infty}^{*}$, we conclude that $g\left(\lambda_{n}\right) \in o_{K}$ for all $n \geq 0$. Hence $h \in \sum_{n=0}^{m} o_{K} t_{n} \subseteq \check{R}$ and $g=\operatorname{ev}(h) \in \operatorname{ev}(\check{R})$. Hence $\mu_{K}^{-1}(R \llbracket Z \rrbracket)_{\infty}^{*} \subseteq \operatorname{ev}(\check{R})$.

Conversely, take $\lambda \in \mu_{K}^{-1}(R \llbracket Z \rrbracket)$. Then $\lambda(\check{R}) \subseteq o_{K}$ by Corollary 4.2.13 and thus for all $g \in \check{R}, \operatorname{ev}(g)(\lambda)=\lambda(g) \in o_{K}$. Hence $\operatorname{ev}(\check{R}) \subseteq \mu_{K}^{-1}(R \llbracket Z \rrbracket)_{\infty}^{*}$.

Corollary 4.2.16. Let $S \subseteq R$ be two admissible subalgebras of $K[\Omega]$. Then $\check{R} \subseteq \check{S}$.

Proof. We have $\mu_{K}^{-1}(S \llbracket Z \rrbracket) \subseteq \mu_{K}^{-1}(R \llbracket Z \rrbracket)$, so $\mu_{K}^{-1}(R \llbracket Z \rrbracket)_{\infty}^{*} \subseteq \mu_{K}^{-1}(S \llbracket Z \rrbracket)_{\infty}^{*}$ by Lemma 4.1.6(2). Hence $\operatorname{ev}(\check{R}) \subseteq \operatorname{ev}(\breve{S})$ by Theorem 4.2.15. Hence $\check{R} \subseteq \check{S}$ because ev is an isomorphism by Corollary 4.1.12.

Note that Theorem 4.2.15 implies that the $o_{K}$-module $\check{R}$ depends only on the admissible subalgebra $R$ and not the particular choice of regular basis $\left\{b_{n}(\Omega): n \geq 0\right\}$ for $R$.
Lemma 4.2.17. If $\lambda \in D^{L-a n}\left(o_{L}, K\right)$, then $\lambda \in o_{K} \llbracket o_{L} \rrbracket$ if and only if we have $\lambda\left(\operatorname{Int}\left(o_{L}, o_{K}\right)\right) \subseteq o_{K}$.
Proof. Suppose that $\lambda\left(\operatorname{Int}\left(o_{L}, o_{K}\right)\right) \subseteq o_{K}$. The $\pi$-adic completion of $I$ is naturally isomorphic to the ring $\mathcal{C}^{0}\left(o_{L}, o_{K}\right)$ of $o_{K}$-valued continuous functions on $o_{L}$. Since $\lambda(I) \subseteq o_{K}, \lambda$ extends to an $o_{K}$-linear form $\tilde{\lambda}: \mathcal{C}^{0}\left(o_{L}, o_{K}\right) \rightarrow$ $o_{K}$ which is automatically continuous. View $\tilde{\lambda}$ as an element of $o_{K} \llbracket o_{L} \rrbracket=$ $D^{\text {cts }}\left(o_{L}, K\right)$. The restrictions of $\tilde{\lambda}$ and of $\lambda \in D^{L-\text { an }}\left(o_{L}, K\right)$ to $K[Y]$ agree by
construction. Since $K[Y]$ is dense in $C^{\text {an }}\left(o_{L}, K\right)$, we conclude that $\lambda$ lies in $o_{K} \llbracket o_{L} \rrbracket$.

Conversely, if $\lambda \in o_{K} \llbracket o_{L} \rrbracket=\mathcal{C}^{0}\left(o_{L}, o_{K}\right)^{*}$, then $\lambda$ must take integer values on $\operatorname{Int}\left(o_{L}, o_{K}\right) \subset \mathcal{C}^{0}\left(o_{L}, o_{K}\right)$.

Theorem 4.2.18. Let $R$ be an admissible subalgebra of $K[\Omega]$.
We have $\mu_{K}^{-1}(R \llbracket Z \rrbracket)=o_{K} \llbracket o_{L} \rrbracket$ if and only if $\check{R}=I$.
Proof. $(\Leftarrow)$. Suppose that $\check{R}=I$, and take $\lambda \in \mu_{K}^{-1}(R \llbracket Z \rrbracket)$. Then $\lambda(\check{R}) \subseteq o_{K}$ by Corollary 4.2.13. Since $\check{R}=I$, this means that $\lambda(I) \subseteq o_{K}$. Hence $\lambda \in$ $o_{K} \llbracket o_{L} \rrbracket$ by Lemma 4.2.17.
$(\Rightarrow)$. Suppose that $\check{R}<I$. Since $K$ is discretely valued, $K / o_{K}$ is an injective cogenerator of the category of $o_{K}$-modules. Hence $\operatorname{Hom}_{o_{K}}\left(I / \check{R}, K / o_{K}\right)$ is nonzero. So there exists an $o_{K}$-linear map $\lambda: I \rightarrow K$ such that $\lambda(\check{R}) \subseteq o_{K}$, but $\lambda(I) \nsubseteq o_{K}$. Regard $\lambda$ as an element of $\operatorname{Hom}_{K}(K[Y], K)$; then by Proposition 4.2.14, $\lambda$ extends to some $\tilde{\lambda} \in \mathcal{O}^{\circ}\left(\mathfrak{X}_{K}\right)$ such that $\left.\tilde{\lambda}\right|_{K[Y]}=\lambda$. Since $\lambda(\check{R}) \subseteq o_{K}$, using Theorem 4.2.9 we see that $\mu_{K}(\tilde{\lambda}) \in R \llbracket Z \rrbracket$. However, $\tilde{\lambda} \notin o_{K} \llbracket o_{L} \rrbracket$ by Lemma 4.2.17 because $\tilde{\lambda}(I) \nsubseteq o_{K}$, so $\tilde{\lambda} \in \mu_{K}^{-1}(R \llbracket Z \rrbracket) \backslash o_{K} \llbracket o_{L} \rrbracket$.

We will now see what implications the above general results have for particular choices of the admissible subalgebra $R$. Let $B=K[\Omega] \cap o_{\mathbb{C}_{p}}$ be the largest possible admissible subalgebra of $K[\Omega]$, and let $U:=\sum_{n=0}^{\infty} o_{K} P_{n}(\Omega)$ be the smallest possible one. Recall from Example 4.2 .7 that $\left\{P_{n}(\Omega): n \geq 0\right\}$ forms a regular basis for $U$.

## Corollary 4.2.19.

(1) $\check{U}=\operatorname{Int}\left(o_{L}, o_{K}\right)$ if and only if $\mu_{K}^{-1}(U \llbracket Z \rrbracket)=o_{K} \llbracket o_{L} \rrbracket$.
(2) $o_{K} \llbracket o_{L} \rrbracket=\Lambda_{K}(\mathfrak{X})$ if and only if $\dot{B}=\operatorname{Int}\left(o_{L}, o_{K}\right)$.

Proof. (1) This is an immediate consequence of Theorem 4.2 .18 with $R=U$.
(2) Theorem 4.2.18 tells us that $\check{B}=I$ if and only if $o_{K} \llbracket o_{L} \rrbracket=\mu_{K}^{-1}(B \llbracket Z \rrbracket)$. However $\mu_{K}^{-1}(B \llbracket Z \rrbracket)=\mu_{K}^{-1}\left(\mathbb{C}_{p} \llbracket Z \rrbracket^{G_{L}, *} \cap B \llbracket Z \rrbracket\right)$ since $\mu_{K}\left(\mathcal{O}(\mathfrak{X})_{K}\right)$ is fixed by the twisted $G_{L}$-action on $\mathbb{C}_{p} \llbracket Z \rrbracket$ by Lemma 4.2.1. Hence $\mu_{K}^{-1}(B \llbracket Z \rrbracket)=$ $\mu_{K}^{-1}\left(o_{\mathbb{C}_{p}} \llbracket Z \rrbracket^{G_{L}, *}\right)=\Lambda_{K}(\mathfrak{X})$ by Corollary 4.2.2, and the result follows.

Recall the matrix coefficients $\sigma_{i, j}(a)$ from Corollary 3.2.6.
Lemma 4.2.20. Let $R=U$ and let $b_{n}:=P_{n}$ for each $n \geq 0$. Then
(1) $\rho_{i j}(Y)=\sigma_{i, j}(Y)$ for all $j \geq i \geq 0$, and
(2) $[a](Z)^{i}=\sum_{j=i}^{\infty} \sigma_{i, j}(a) Z^{j}$ for any $a \in o_{L}, i \geq 0$.

Proof. (1) This follows by comparing Corollary 3.2.6 with Lemma 4.2.8(1).
(2) Using Definition 3.2.1(5) and Lemma 3.2.3 we see that $\left\langle P_{k}(s), Z^{i}\right\rangle=\delta_{k i}$ for all $i, k \geq 0$. By Corollary 3.2 .6 we have $P_{j}(a s)=\sum_{k=0}^{j} \sigma_{k j}(a) P_{k}(s)$. Fix
$i \geq 0$ and apply $\left\langle-, Z^{i}\right\rangle$ to this equation: using equation (4) we then have

$$
\sigma_{i, j}(a)=\left\langle\sum_{k=0}^{j} \sigma_{k j}(a) P_{k}(s), Z^{i}\right\rangle=\left\langle P_{j}(a s), Z^{i}\right\rangle=\left\langle P_{j}(s),[a](Z)^{i}\right\rangle
$$

Hence $\sigma_{i, j}(a)$ is precisely the coefficient of $Z^{j}$ in the power series $[a](Z)^{i}$.
This justifies the definition of the polynomials $\sigma_{i, j}(Y)$ which was given in $\S 1.5$. We can now give the proof of Theorem 1.5.1 from the Introduction.
Theorem 4.2.21. If $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$, then $\mathrm{Pol}=\mathrm{Int}$.
Proof. Note that $\mathrm{Pol}=\check{U}$, in view of Lemma 4.2.20(1) and Definition 4.2.12. Now $\Lambda_{L}(\mathfrak{X})=\mathcal{O}^{\circ}\left(\mathfrak{X}_{L}\right)$, so if this is equal to $o_{L} \llbracket o_{L} \rrbracket$, then $\check{B}=\operatorname{Int}\left(o_{L}, o_{L}\right)$ by Corollary 4.2.19(2). But $U \subseteq B$, so $\check{B} \subseteq \check{U} \subseteq \operatorname{Int}\left(o_{L}, o_{L}\right)$ by Corollary 4.2.16. Hence $\check{U}=\operatorname{Int}\left(o_{L}, o_{L}\right)$ as claimed.
4.3. Calculating the matrix coefficients $\sigma_{i, j}(Y)$. Here we will assume that the coordinate $Z$ on the Lubin-Tate formal group is chosen in such a way that

$$
\log _{L T}(Z)=\sum_{n=0}^{\infty} \frac{Z^{q^{n}}}{\pi^{n}}
$$

It turns out that the polynomials $P_{j}(s)$ are sparse: the coefficient of $s^{i}$ in $P_{j}(s)$ is non-zero only if $i \equiv j \bmod (q-1)$. We will obtain more information about these coefficients; this will require developing some notation to deal with this sparsity. The calculations that follow rest on the following observation.

Proposition 4.3.1. For every $n \geq 0$, we have

$$
P_{n}(Y)=\sum_{k_{0}+q k_{1}+\cdots+q^{d} k_{d}=n} \frac{Y^{k_{0}+\cdots+k_{d}}}{k_{0}!\cdots k_{d}!\cdot \pi^{1 \cdot k_{1}+2 \cdot k_{2}+\cdots+d \cdot k_{d}}}
$$

Proof. If $\log _{\mathrm{LT}}(Z)=\sum_{k=0}^{\infty} Z^{q^{k}} / \pi^{k}$ and exp is the usual exponential, then

$$
\begin{aligned}
\sum_{n=0}^{\infty} P_{n}(Y) Z^{n}=\exp \left(Y \cdot \log _{\mathrm{LT}}(Z)\right)=\prod_{\ell \geq 0} \exp (Y \cdot & \left.Z^{q^{\ell}} / \pi^{\ell}\right) \\
& =\prod_{\ell \geq 0} \sum_{k \geq 0}\left(Y \cdot Z^{q^{\ell}} / \pi^{\ell}\right)^{k} / k!
\end{aligned}
$$

The coefficient of $Z^{n}$ in this product is the sum of $Y^{k_{0}+\cdots+k_{d}} / k_{0}!\cdots k_{d}!$. $\pi^{1 \cdot k_{1}+2 \cdot k_{2}+\cdots+d \cdot k_{d}}$ over all tuples $\left(k_{0}, \cdots, k_{d}\right)$ of positive integers such that $k_{0}+q k_{1}+\cdots+q^{d} k_{d}=n$.

The following formula for the derivative $\frac{d}{d Y} P_{n}(Y)$ will be very useful in the calculations.

Proposition 4.3.2. For every $n \geq 0$, we have $\frac{d}{d Y} P_{n}(Y)=\sum_{k \geq 0} \pi^{-k}$. $P_{n-q^{k}}(Y)$.

Proof. We have $P_{n}(Y+Z)=P_{n}(Y)+\sum_{j=1}^{n} P_{j}(Z) P_{n-j}(Y)$ by [28, Lemma 4.2(4)]. Hence it is enough to determine which $P_{j}(Z)$ have a term of degree 1 in them, and what the corresponding coefficient is in this case. The answer now follows from Proposition 4.3.1.

We fix $m \in\{0,1,2, \cdots, q-2\}$ from now on. We will use the convenient notation

$$
\underline{i}:=m+i(q-1) \quad \text { for all } \quad i \geq 0
$$

Definition 4.3.3. For each $j \geq i \geq 0$, we define

$$
\begin{gathered}
Q_{m}(i, j):=\left\{\mathbf{k} \in \mathbb{N}^{\infty}: \sum_{\ell=0}^{\infty} k_{\ell}=\underline{i}, \quad \sum_{\ell=1}^{\infty} k_{\ell}\left(\frac{q^{\ell}-1}{q-1}\right)=j-i\right\}, \quad \text { and } \\
r_{i, j}^{(m)}:=\sum_{\mathbf{k} \in Q_{m}(i, j)}\binom{\underline{i}}{k_{0} ; k_{1} ; k_{2} ; \cdots} \cdot \pi^{-\sum_{\ell=1}^{\infty} \ell \cdot k_{\ell}} .
\end{gathered}
$$

Here $\left({ }_{k_{0} ; k_{1} ; k_{2} ; \cdots}\right)=\frac{(i)!}{k_{0}!\cdot k_{1}!\cdot k_{2}!\cdots}$ is the multinomial coefficient.
Lemma 4.3.4. We have $r_{j j}^{(m)}=1$ for all $j \geq 0$.
Proof. If $i=j$, then the second condition on a vector $\mathbf{k} \in \mathbb{N}^{\infty}$ to lie in $Q_{m}(i, j)$ forces $k_{1}=k_{2}=\cdots=0$ because $\frac{q^{\ell}-1}{q-1}>0$ for all $\ell \geq 1$. But then $k_{0}=\underline{i}=\underline{j}$ from the first condition, so the formula for $r_{j j}^{(m)}$ collapses to give 1 .
Proposition 4.3.5. Let $n=\underline{j}$ for some $j \geq 0$. Write

$$
P_{n}(s)=\sum_{k=0}^{n} b_{k}^{(n)} s^{k}
$$

with $b_{k}^{(n)} \in L$ for $k=0, \ldots, n$.
(1) We have $b_{k}^{(n)}=0$ if $k \not \equiv n \bmod (q-1)$.
(2) For each $0 \leq i \leq j$, we have $b_{\underline{i}}^{(\underline{j})}=\frac{r_{i, j}^{(m)}}{\underline{i}!}$.

Proof. By Proposition 4.3.1, the coefficient $b_{k}^{(n)}$ of $s^{k}$ in $P_{n}(s)$, is given by

$$
b_{k}^{(n)}=\sum_{\mathbf{k}} \frac{1}{\left(k_{0}!k_{1}!k_{2}!\cdots\right) \pi^{0 \cdot k_{0}+1 \cdot k_{1}+2 \cdot k_{2}+\cdots}}
$$

where the sum runs over all possible sequences $\mathbf{k}=\left(k_{0}, k_{1}, k_{2}, \cdots\right)$ of nonnegative integers satisfying the following two conditions:

$$
k_{0}+k_{1}+k_{2}+\cdots=k, \quad \text { and } \quad k_{0}+q k_{1}+q^{2} k_{2}+\cdots=n
$$

Of course given any such sequence, necessarily $k_{\ell}$ must be zero for all sufficiently large $\ell$ depending only on $n$ and $k$, and the set of solutions to these equations is always finite, so the sum of all these fractions makes sense.

Next note that if $k_{0}, k_{1}, \cdots$ satisfies these two conditions, then necessarily

$$
n \equiv k \quad \bmod (q-1)
$$

This implies part (1). For part (2), let $k=\underline{i}$ and $n=\underline{j}$, and suppose that the non-negative integers $k_{0}, k_{1}, \cdots$ satisfy $k_{0}+k_{1}+\cdots=k$; then subtracting gives
$k_{0}+q k_{1}+q^{2} k_{2}+\cdots=m+(q-1) j \Leftrightarrow(q-1) k_{1}+\left(q^{2}-1\right) k_{2}+\cdots=(q-1)(j-i)$.
In this way, we see that $Q_{m}(i, j)$ is precisely the set of sequences that contribute to the coefficient of $s^{\underline{i}}$ in $P_{\underline{j}}(s)$. This coefficient is then

$$
b_{k}^{(n)}=\frac{1}{k!} \sum_{k \in Q_{m}(i, j)} \frac{k!}{k_{0}!k_{1}!\cdots} \cdot \pi^{-\sum_{\ell=1}^{\infty} \ell \cdot k_{\ell}}=\frac{r_{i, j}^{(m)}}{k!} .
$$

Lemma 4.3.6. Suppose that $j \geq i \geq 0$. Then $r_{i j}^{(m)}$ is the coefficient of $Z^{\underline{j}}$ in $\log _{L T}(Z)^{\underline{i}}$.

Proof. Write $\log _{L T}(Z)^{k}=\sum_{n=k}^{\infty} d_{n}^{(k)} Z^{n}$. Then

$$
\begin{aligned}
& \sum_{n=0}^{\infty} P_{n}(Y) Z^{n}=\exp \left(Y \log _{L T}(Z)\right)=\sum_{k=0}^{\infty} \frac{1}{k!} \log _{L T}(Z)^{k} Y^{k} \\
&=\sum_{k=0}^{\infty} \frac{1}{k!} \sum_{n=k}^{\infty} d_{n}^{(k)} Z^{n} Y^{k}
\end{aligned}
$$

Equating the coefficent of $Z^{n} Y^{k}$ shows that

$$
b_{k}^{(n)}=\frac{1}{k!} d_{n}^{(k)} \quad \text { for } 1 \leq j \leq n
$$

Applying Proposition 4.3.5(2), we have $r_{i, j}^{(m)}=\underline{i}!b_{\underline{i}}^{(\underline{j})}=d_{\underline{j}}^{(\underline{i})}$.
Corollary 4.3.7. Define polynomials $R_{j}^{(m)}(t) \in L[t]$ for $j \geq 0$ by the formula

$$
R_{j}^{(m)}(t):=\sum_{i=0}^{j} \frac{r_{i, j}^{(m)}}{(\underline{i})!} t^{i} .
$$

Then for all $j \geq 0$ we have $P_{\underline{j}}(s)=s^{m} \cdot R_{j}^{(m)}\left(s^{q-1}\right)$.
Lemma 4.3.8. For each $j \geq i \geq 0$ there exist $\sigma_{i, j}(Y) \in \operatorname{Int}\left(o_{L}, o_{L}\right)$ such that

$$
P_{j}(Y s)=\sum_{i=0}^{j} \sigma_{i, j}(Y) P_{i}(s)
$$

Proof. By Example 4.2.7, $\left\{P_{n}(\Omega): n \geq 0\right\}$ forms a regular basis for the admissible subalgebra $\sum_{n=0}^{\infty} o_{K} P_{n}(\Omega)$ of $L[\Omega]$. Apply Lemma 4.2.8 and use the transcendence of $\Omega$ over $L$.

Of course this is just another way of rephrasing Corollary 3.2.6. We will now see that the matrix of polynomials $\left(\sigma_{i, j}(Y)\right)_{i, j}$ is sparse as well.
Proposition 4.3.9. Let $j \geq 0$ and suppose that $0 \leq k \leq \underline{j}$.
(1) $\sigma_{k, \underline{j}}(Y)=0$ if $k \not \equiv m \bmod (q-1)$.
(2) For each $i=0, \ldots, j$ there exists $\tau_{i, j}^{(m)}(X) \in L[X]$ such that

$$
\sigma_{\underline{i}, \underline{j}}(Y)=Y^{m} \cdot \tau_{i, j}^{(m)}\left(Y^{q-1}\right)
$$

Proof. Using Lemma 4.3.8, we have

$$
P_{\underline{j}}(Y s)=\sum_{k=0}^{\underline{j}} \sigma_{k, \underline{j}}(Y) P_{k}(s) .
$$

Dividing both sides by $Y^{m} s^{m}$ we obtain an equality of Laurent polynomials

$$
\begin{equation*}
R_{j}^{(m)}\left(Y^{q-1} s^{q-1}\right)=\sum_{k=0}^{\underline{j}} Y^{-m} \sigma_{k, \underline{j}}(Y) \cdot s^{-m} P_{k}(s) \tag{16}
\end{equation*}
$$

The left hand side of (16) is a polynomial in $s^{q-1}$ with coefficients in $L[Y]$. The Laurent polynomial $s^{-m} P_{k}(s)$ lies in $s^{k-m} L\left[s^{q-1}, s^{1-q}\right]$ by Proposition 4.3.5. Since

$$
L[Y]\left[s, s^{-1}\right]=\bigoplus_{c=0}^{q-2} s^{c} L[Y]\left[s^{q-1}, s^{1-q}\right]
$$

looking at the component of the right hand side of (16) that lies in the space $s^{c} L[Y]\left[s^{q-1}, s^{1-q}\right]$ for $c \in\{1, \cdots, q-2\}$ and then looking at the leading coeffiicent of $s^{-m} P_{k}(s)$ implies (1).

Using Corollary 4.3.7, we can now rewrite (16) as follows:

$$
\begin{equation*}
R_{j}^{(m)}\left(Y^{q-1} s^{q-1}\right)=\sum_{i=0}^{j} Y^{-m} \sigma_{\underline{i}, \underline{j}}(Y) \cdot R_{i}^{(m)}\left(s^{q-1}\right) \tag{17}
\end{equation*}
$$

Since the left hand side of (17) is now a polynomial in $Y^{q-1}$ with coefficients in $L\left[s^{q-1}\right]$, we deduce by looking at the right hand side of (17) that the $a$ priori Laurent polynomial $Y^{-m} \sigma_{\underline{i}, \underline{j}}(Y)$ in $Y$ in fact lies in $L\left[Y^{q-1}\right]$. Part (2) follows.

Setting $t=s^{q-1}$ and $X=Y^{q-1}$, we deduce the following
Corollary 4.3.10. The polynomials $R_{j}^{(m)}(t X)$ satisfy

$$
R_{j}^{(m)}(t X)=\sum_{i=0}^{j} \tau_{i, j}^{(m)}(X) R_{i}^{(m)}(t)
$$

Definition 4.3.11. Consider the following infinite upper-triangular matrices.
(1) $\left[r^{(m)}\right]_{i j}=r_{i j}^{(m)}$ for $j \geq i \geq 0$,
(2) $\mathcal{T}_{i j}^{(m)}=\tau_{i, j}^{(m)}(X)$, and
(3) $\mathcal{D}_{X}:=\operatorname{diag}\left(1, X, X^{2}, \cdots\right)$.

Lemma 4.3.12. We have the matrix equation

$$
r^{(m)} \cdot \mathcal{T}^{(m)}=\mathcal{D}_{X} \cdot r^{(m)}
$$

Proof. Note that each matrix appearing on the right hand side has infinitely many rows and columns, but each one is also upper triangular, so matrix multiplication makes sense. Moreover, as $r_{j j}^{(m)}=1$ for all $j \geq 0$ by Lemma 4.3.4, the matrix $r^{(m)}$ is invertible, with inverse matrix having entries in $L$.

Substitute the definition of $R_{j}^{(m)}(t)$ from Corollary 4.3.7 into Corollary 4.3.10 to obtain

$$
\sum_{\ell=0}^{j} \frac{r_{\ell, j}^{(m)}}{(\underline{\ell})!} t^{\ell} X^{\ell}=\sum_{i=0}^{j} \tau_{i, j}^{(m)}(X) \sum_{\ell=0}^{i} \frac{r_{\ell, i}^{(m)}}{(\underline{\ell})!} t^{\ell}
$$

Equate the coefficients of $t^{\ell}$ to get

$$
r_{\ell, j}^{(m)} X^{\ell}=\sum_{i=0}^{j} \tau_{i, j}^{(m)}(X) \cdot r_{\ell, i}^{(m)}
$$

The right hand side is the $(\ell, j)$-th entry of $r^{(m)} \cdot \mathcal{T}^{(m)}$. The left hand side is the $(\ell, j)$-th entry of $\mathcal{D}_{X} \cdot r^{(m)}$. The result follows.

The following two results on the coefficients $r_{i, j}^{(m)}$ are strictly speaking not needed for the calculations appearing in Appendix A, but they are nevertheless interesting in their own right.

Lemma 4.3.13. For each $j \geq i \geq 0$, we have

$$
r_{i, j}^{(m)}=\left(\sum_{k \in Q_{m}(i, j)}\binom{\underline{i}}{k_{0} ; k_{1} ; \cdots} \pi^{\sum_{\ell=1}^{\infty} k_{\ell}\left(\frac{q^{\ell}-1}{q-1}-\ell\right)}\right) \cdot \pi^{i-j} .
$$

Proof. Let $\mathbf{k} \in Q_{m}(i, j)$. Then $\sum_{\ell=1}^{\infty} k_{\ell}\left(\frac{q^{\ell}-1}{q-1}\right)=j-i$, and therefore

$$
\pi^{\sum_{\ell=1}^{\infty} k_{\ell}\left(\frac{q^{\ell}-1}{q-1}-\ell\right)} \cdot \pi^{i-j}=\pi^{j-i} \cdot \pi^{-\sum_{\ell=1}^{\infty} \ell k_{\ell}} \cdot \pi^{i-j}=\pi^{-\sum_{\ell=1}^{\infty} \ell k_{\ell}} .
$$

The result now follows from Definition 4.3.3.
Proposition 4.3.14. Let $j \geq i \geq 0$. Then
(1) $\pi^{j-i} \cdot r_{i, j}^{(m)} \in o_{L}$, and
(2) $\pi^{j-i} \cdot r_{i, j}^{(m)} \equiv(\underset{j-i}{\underline{i}}) \bmod \pi^{q-1} o_{L}$.

Proof. (1) Note that for every $\ell \geq 1$ we have

$$
\begin{aligned}
\alpha_{\ell}:=\frac{q^{\ell}-1}{q-1}-\ell & =\frac{(1+(q-1))^{\ell}-1}{q-1}-\ell=\frac{1+\ell(q-1)+\binom{\ell}{2}(q-1)^{2}+\cdots+(q-1)^{\ell}-1}{q-1}-\ell . \\
& =\binom{\ell}{2}(q-1)+\binom{\ell}{3}(q-1)^{2}+\cdots+(q-1)^{\ell-1}
\end{aligned}
$$

Thus $\alpha_{\ell} \geq 0$ always. Hence the expression in the big brackets in Lemma 4.3.13 lies in $o_{L}$.
(2) The exponent of $\pi$ appearing in the term in the sum corresponding to $\mathbf{k} \in$ $Q_{m}(i, j)$ is equal to $\sum_{\ell=1}^{\infty} k_{\ell} \alpha_{\ell}$. It follows from the formula for $\alpha_{\ell}$ established above that $\alpha_{1}=0$. Hence this exponent is a positive multiple of $q-1$, unless $k_{\ell}=0$ for all $\ell \geq 2$. In this case, the exponent is 0 and the corresponding term is equal to $\left({\underset{j}{i}}_{j-i}\right)$ because in this case $k_{1}=\sum_{\ell=1}^{\infty} k_{\ell} \frac{q^{\ell}-1}{q-1}=j-i$.

## 5. Consequences of the Katz isomorphism

5.1. Equivariant endomorphisms of $L_{\infty}$. Throughout this $\S$, we assume that $L=\mathbb{Q}_{p^{2}}$ and that $\pi=p$. In particular, $L_{\infty}$ is the completion of $L\left(\mathcal{G}\left[p^{\infty}\right]\right)$. We recall the statement of the Katz isomorphism (Theorem 3.6.15): if $S$ is a $\pi$-adically complete $o_{L}$-algebra, then the map

$$
\mathcal{K}^{*}: \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), S\right) \rightarrow S \llbracket Z \rrbracket^{\psi_{q}-\mathrm{int}}
$$

is an isomorphism. Recall ([19], page 58), that $\mu$ is said to be supported in $o_{L}^{\times}$ if and only if $\mu(f)=0$ for all $f$ such that $f=0$ on $o_{L}^{\times}$. We have the following criterion.

Lemma 5.1.1. A measure $\mu \in \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), S\right)$ is supported in $o_{L}^{\times}$if and only if $\psi_{q}\left(\mathcal{K}^{*}(\mu)\right)=0$.

Proof. Note that $f \in \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$ is zero on $o_{L}^{\times}$if and only if $f=\psi_{C}(g)$ for some $g \in \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$. Indeed, $\psi_{C}(g)(a)=0$ if $a \in o_{L}^{\times}$by definition, and if $f=0$ on $o_{L}^{\times}$, then $f=\psi_{C} \varphi_{C}(f)$.

The map $\mathcal{K}^{*}$ is injective by Theorem 3.6.15. By Corollary 3.3.7, we have $\psi_{q} \mathcal{K}^{*}=\mathcal{K}^{*} \psi_{C}^{*}$. Hence $\psi_{q} \mathcal{K}^{*}(\mu)=0 \Leftrightarrow \mathcal{K}^{*} \psi_{C}^{*}(\mu)=0 \Leftrightarrow \psi_{C}^{*}(\mu)=0 \Leftrightarrow$ $\mu\left(\psi_{C}(g)\right)=0$ for all $g \Leftrightarrow \mu$ is supported in $o_{L}^{\times}$.

There is the usual $G_{L}, *$ action on $o_{\mathbb{C}_{p}} \llbracket Z \rrbracket$, and on $\operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right)$ it is given by $g^{*}(\mu)(f)=g\left(\mu\left(g^{-1}(f)\right)\right)=g\left(\mu\left(a \mapsto f\left(\tau(g)^{-1} \cdot a\right)\right)\right.$ since $f$ is Gal continuous. In particular, Theorem 3.6.15 applied with $S=o_{\mathbb{C}_{p}}$ implies the following.

Corollary 5.1.2. We have
(1) $\operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right)^{G_{L}, *}=\Lambda_{L}(\mathfrak{X})^{\psi_{q} \text {-int }}$.
(2) $\operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right)^{G_{L}, *}=\Lambda_{L}(\mathfrak{X})^{\psi_{q}=0}$.

Since $L=\mathbb{Q}_{p^{2}}$, the map $\tau$ is surjective. Let $\Gamma_{L}=\operatorname{Gal}\left(L\left(\mathcal{G}\left[p^{\infty}\right]\right) / L\right)$.
Lemma 5.1.3. The map $\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right) \rightarrow o_{\infty}$ given by $f \mapsto f(1)$ is an isomorphism of $o_{L}$-modules.

Proof. Since $d=2$, we know that $\tau$ is surjective by Lemma 2.6.4. Now, if $x \in o_{\infty}$, let $f_{x} \in \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right)$ be given by $f_{x}(1)=x$ and $f_{x}(\tau(g))=g(x)$. Every element of $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right)$ is of this form.

Theorem 3.6.15 applied with $S=o_{L}$ now gives us the following
Theorem 5.1.4. The map $\mathcal{K}^{*}$ gives rise to an $o_{L}$-linear isomorphism $o_{\infty}^{*} \simeq$ $o_{L} \llbracket Z \rrbracket^{\psi_{q}=0}$.
Proposition 5.1.5. The space $\operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right)^{G_{L}, *}$ is naturally isomorphic to the space of $\Gamma_{L}$-equivariant $o_{L}$-linear maps $o_{\infty} \rightarrow o_{\infty}$.

Proof. If $x \in o_{\infty}$, let $f_{x} \in \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right)$ be as in the proof of Lemma 5.1.3 above. If $\mu \in \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right)^{G_{L}, *}$, we define a map $T: o_{\infty} \rightarrow o_{\infty}$ by $T(x)=\mu\left(f_{x}\right)$. We have $f_{x+y}=f_{x}+f_{y}$ and $f_{a x}=a f_{x}$ if $a \in o_{L}$ so that $T$ is $o_{L}$-linear. In addition, $T$ is $\Gamma_{L}$-equivariant because $\mu$ is fixed under the $G_{L}, *$-action. Indeed, $g(T(x))=g\left(\mu\left(f_{x}\right)\right)=\mu\left(g\left(f_{x}\right)\right)$ and $g\left(f_{x}\right)(1)=g(x)$ so that $g\left(f_{x}\right)=f_{g(x)}$. Therefore, $g(T(x))=T(g(x))$.

Conversely, a $\Gamma_{L}$-equivariant $o_{L}$-linear map $T: o_{\infty} \rightarrow o_{\infty}$ as above gives an element $\mu \in \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right)^{G_{L}, *}$ via $\mu\left(f_{x}\right)=T(x)$.

Combining Corollary 5.1.2 and Proposition 5.1.5, we get the following.
Theorem 5.1.6. We have $\operatorname{End}_{o_{L}}^{G_{L}}\left(o_{\infty}\right) \simeq \Lambda_{L}(\mathfrak{X})^{\psi_{q}=0}$.
Corollary 5.1.7. We have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if every $\Gamma_{L}$-equivariant $o_{L}$-linear map $o_{\infty} \rightarrow o_{\infty}$ comes from an element of $o_{L} \llbracket \Gamma_{L} \rrbracket$.

Proof. We have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if $\Lambda_{L}(\mathfrak{X})^{\psi=0}=\Lambda\left(o_{L}^{\times}\right)$by Lemma 5.1.9 below. If $\mu \in \Lambda_{L}(\mathfrak{X})^{\psi=0}$, then by Corollary 5.1.2 it corresponds to an element of $\operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\mathrm{Gal}}^{0}\left(o_{L}^{\times}, o_{\mathbb{C}_{p}}\right), o_{\mathbb{C}_{p}}\right)^{G_{L}, *}$. By Proposition 5.1.5, the element $\mu \in \Lambda_{L}(\mathfrak{X})^{\psi=0}$ comes from an element $\nu \in o_{L} \llbracket \Gamma_{L} \rrbracket$. The element $\mu$ then corresponds to the image of $\nu$ in $\Lambda\left(o_{L}^{\times}\right)$via $\tau$. Indeed, if $g \in \Gamma_{L}$ and $T$ is given by $x \mapsto g(x)$, then it corresponds to $\mu: f_{x} \mapsto g(x)$ and $g(x)=f_{x}(\tau(g))$ so that $\mu=\delta_{\tau(g)}$.

Using Corollary 5.1.7, we get the following
Theorem 5.1.8. We have $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$ if and only if every continuous $L$ linear and $G_{L}$-equivariant map $f: L_{\infty} \rightarrow L_{\infty}$ comes from the Iwasawa algebra $L \otimes_{o_{L}} o_{L} \llbracket \Gamma_{L} \rrbracket$.
Proof. Indeed, by Corollary 2.10.11, $\Lambda_{L}(\mathfrak{X}) \cap\left(L \otimes_{o_{L}} o_{L} \llbracket o_{L} \rrbracket\right)=o_{L} \llbracket o_{L} \rrbracket$.
Lemma 5.1.9. If $\Lambda_{L}(\mathfrak{X})^{\psi=0}=\Lambda\left(o_{L}^{\times}\right)$, then $\Lambda_{L}(\mathfrak{X})=o_{L} \llbracket o_{L} \rrbracket$.
Proof. If $f \in \Lambda_{L}(\mathfrak{X})$, then $\delta_{1} \cdot \varphi(f) \in \Lambda_{L}(\mathfrak{X})^{\psi=0}$. So $\varphi(f) \in o_{L} \llbracket o_{L} \rrbracket$ and $f=\psi_{q} \varphi(f) \in o_{L} \llbracket o_{L} \rrbracket$.

The following proposition implies that there are no "Tate trace maps" $L_{\infty} \rightarrow$ $L$ or $L_{\infty} \rightarrow L_{n}$ (recall that $L_{\infty}$ is the completion of $L\left(\mathcal{G}\left[p^{\infty}\right]\right)$ ).
Proposition 5.1.10. Let $f: L_{\infty} \rightarrow L_{\infty}$ be a continuous, $\Gamma_{L}$-equivariant and L-linear map. If $f\left(L_{\infty}\right)$ is included in a finite field extension of $L$, then $f(1)=0$.

Proof. We have $\log \Omega \in L_{\infty}$ and $(g-1) \log \Omega=\log \tau(g)$ if $g \in \Gamma_{L}$. Hence

$$
(g-1) f(\log \Omega)=f((g-1) \log \Omega)=f(\log \tau(g))=\log \tau(g) \cdot f(1)
$$

Hence if $f(1) \neq 0$, then $f(\log \Omega)$ cannot belong to a finite extension of $L$.
Note that a similar result was proved by Fourquaux, see for instance [14, Prop 2.2.1]. Proposition 5.1.10 can be strengthened: almost the same proof gives us the following proposition. Recall that $L_{\infty}^{\Gamma_{L_{n}}}=L_{n}$ by the Ax-Sen-Tate theorem, see Theorem 1 on page 176 of [32].

Proposition 5.1.11. Let $f: L_{\infty} \rightarrow L_{\infty}$ be a continuous, $\Gamma_{L}$-equivariant and $L$-linear map. If $f \neq 0$, then there exists $a_{1} \neq 0, a_{0} \in L\left(\mathcal{G}\left[p^{\infty}\right]\right)$ such that $f\left(L_{\infty}\right)$ contains $a_{1} \log \Omega+a_{0}$.

Proof. We have $\log \Omega \in L_{\infty}$ and $(g-1) \log \Omega=\log \tau(g)$ if $g \in \Gamma_{L}$. Take $x \in L\left(\mathcal{G}\left[p^{\infty}\right]\right)$ such that $f(x) \neq 0$, and choose (note that $f\left(L_{n}\right) \subset L_{n}$ by the Ax-Sen-Tate theorem) some $n$ such that $x, f(x) \in L_{n}$. If $g \in \Gamma_{n}$, then

$$
(g-1) f(x \cdot \log \Omega)=f((g-1)(x \cdot \log \Omega))=f(x \cdot \log \tau(g))=\log \tau(g) \cdot f(x)
$$

Therefore $(g-1)(f(x \cdot \log \Omega)-f(x) \cdot \log \Omega)=0$ for all $g \in \Gamma_{n}$, so that $f(x$. $\log \Omega)-f(x) \cdot \log \Omega \in L_{n}$ by Ax-Sen-Tate.

We can now take $a_{1}=f(x)$ and $a_{0}=f(x \cdot \log \Omega)-f(x) \cdot \log \Omega$.
This can be strengthened even further. Let $L_{\infty}^{\text {alg }}$ denote the vectors in $L_{\infty}$ that are locally algebraic for the action of the Lie group $\Gamma_{L}$. Let $c(g)=$ $\log \tau(g)=\log \chi_{p}^{\sigma}(g)$. The set $L_{\infty}^{\text {alg }}$ is the set of $x \in L_{\infty}$ such that there exists an open subgroup $\Gamma_{x}$ of $\Gamma_{L}$ and $d \geq 0$ and $x_{0}=x, x_{1}, \ldots, x_{d} \in L_{\infty}$ such that $g(x)=x_{0}+x_{1} c(g)+\cdots+x_{d} c(g)^{d}$ if $g \in \Gamma_{x}$. Note that technically, these are the locally $\sigma$-analytic locally algebraic vectors in $L_{\infty}$. However since $L=\mathbb{Q}_{p^{2}}$, every locally analytic vector of $L_{\infty}$ is locally $\sigma$-analytic (see [4]).

Lemma 5.1.12. We have $L_{\infty}^{\text {alg }}=L\left(\mathcal{G}\left[p^{\infty}\right]\right)[\log \Omega]$.
Proof. One inclusion is easy. Now take $x \in L_{\infty}^{\text {alg }}$ and write $g(x)=x_{0}+x_{1} c(g)+$ $\cdots+x_{d} c(g)^{d}$ if $g \in \Gamma_{x}$. On $L_{\infty}^{\text {alg }}$ we have the derivative $\nabla: x \mapsto x_{1}$ and we know (from the theory of locally analytic vectors) that $\nabla^{j}(x) / j!=x_{j}$ for all $j$. In particular, $\nabla\left(x_{d}\right)=0$, so that $x_{d} \in L\left(\mathcal{G}\left[p^{\infty}\right]\right)$. The element $x-x_{d} \log ^{d} \Omega$ is then in $L_{\infty}^{\text {alg }}$ and it is of degree $\leq d-1$, which allows us to prove the Lemma by induction.

We see that $\nabla=\frac{d}{d \log \Omega}$. For all $n$, the map $\nabla: L_{n}[\log \Omega] \rightarrow L_{n}[\log \Omega]$ is surjective, and its kernel is $L_{n}$. If $f: L_{\infty} \rightarrow L_{\infty}$ is a continuous, $\Gamma_{L}$-equivariant and $L$-linear map, then $f\left(L_{\infty}^{\text {alg }}\right) \subset L_{\infty}^{\text {alg }}$. In addition, $\nabla=\lim _{g \rightarrow 1}(g-1) / c(g)$ so that $f \circ \nabla=\nabla \circ f$.

Proposition 5.1.13. Let $f: L_{\infty} \rightarrow L_{\infty}$ be a continuous, $\Gamma_{L}$-equivariant and $L$-linear map. If $f \neq 0$, there exists $n \geq 0$ such that $L_{n} \cdot f\left(L_{n}[\log \Omega]\right)$ contains $L_{n}[\log \Omega]$.

Proof. Take $x \in L\left(\mathcal{G}\left[p^{\infty}\right]\right)$ such that $f(x) \neq 0$ and let $n \geq 0$ be such that $x, f(x) \in L_{n}$. We prove by induction on $d$ that $L_{n} \cdot f\left(L_{n}[\log \Omega]\right)$ contains $L_{n}[\log \Omega]_{\operatorname{deg} \leq d}$. In order to do this, we prove that $f\left(x \cdot \log ^{d} \Omega\right)$ is a polynomial (in $\log \Omega$ ) of degree $d$. The case $d=0$ follows from the fact that $f(x) \neq 0$. Now assume that the result holds for $d-1$. We have

$$
\nabla f\left(x \cdot \log ^{d} \Omega\right)=f\left(x \cdot \nabla \log ^{d} \Omega\right)=f\left(d x \cdot \log ^{d-1} \Omega\right)
$$

so that $f\left(x \cdot \log ^{d} \Omega\right)$ is a polynomial of degree $d$. This implies the claim.
5.2. The dual of the ring of integers of a $p$-adic Lie extensions. Recall that $\pi \in o_{L}$ is a uniformiser and $k_{L}:=o_{L} / \pi o_{L}$ is the residue field of $L$. In this $\S, L_{\infty} / L$ is an infinite Galois extension with Galois group $\Gamma=\operatorname{Gal}\left(L_{\infty} / L\right)$. We fix a chain

$$
\Gamma \supseteq \Gamma_{1} \supseteq \Gamma_{2} \supseteq \cdots
$$

of open normal subgroups of $\Gamma$ such that $\bigcap_{n=1}^{\infty} \Gamma_{n}=1$.
Definition 5.2.1. Let $n \geq 1$.
(1) $L_{n}:=L_{\infty}^{\Gamma_{n}}$, a finite Galois extension of $L$ with Galois group $\Gamma / \Gamma_{n}$.
(2) $o_{n}$ is the integral closure of $o_{L}$ in $L_{n}$.
(3) $o_{n}^{*}:=\operatorname{Hom}_{o_{L}}\left(o_{n}, o_{L}\right)$.
(4) $k_{n}:=o_{n} / \pi o_{n}$.
(5) $k_{n}^{\vee}:=\operatorname{Hom}_{k_{L}}\left(k_{n}, k_{L}\right)$.

Note that $o_{n}$ and $o_{n}^{*}$ are naturally $o_{L}\left[\Gamma / \Gamma_{n}\right]$-modules, both free of finite rank as an $o_{L}$-module, and $k_{n}$ and $k_{n}^{*}$ are $k_{L}\left[\Gamma / \Gamma_{n}\right]$-modules, both finite dimensional over $k_{L}$.
Remark 5.2.2. Let $n \geq 1$.
(1) $o_{n}^{*}$ can be identified with the inverse different $\mathfrak{d}_{L_{n} / L}^{-1}$ of the extension $L_{n} / L$.
(2) Applying the duality functor $(-)^{*}=\operatorname{Hom}_{o_{L}}\left(-, o_{L}\right)$ to the natural inclusion of $o_{L}$-modules $o_{n} \rightarrow o_{n+1}$, we obtain a natural connecting map $o_{n+1}^{*} \rightarrow o_{n}^{*}$. This map is surjective, because the $o_{n+1} / o_{n}$ is a finitely generated and torsion-free $o_{L}$-module.

Lemma 5.2.3. For each $n \geq 1$, there is a short exact sequence of $o_{L}\left[\Gamma / \Gamma_{n}\right]$ modules

$$
0 \rightarrow o_{n}^{*} \xrightarrow{\pi} o_{n}^{*} \rightarrow k_{n}^{\vee} \rightarrow 0 .
$$

Proof. Let $M$ be an $o_{L}$-module and consider the complex of $o_{L}$-modules

$$
0 \rightarrow M^{*} \xrightarrow{\pi} M^{*} \xrightarrow{\eta_{M}}(M / \pi M)^{\vee} \rightarrow 0
$$

where $M^{*}:=\operatorname{Hom}_{o_{L}}\left(M, o_{L}\right),(M / \pi M)^{\vee}=\operatorname{Hom}_{k_{L}}\left(M / \pi M, k_{L}\right)$ and where $\eta_{M}(f)(m+\pi M)=f(m)+\pi o_{L} \in k_{L}$. This complex commutes with finite direct sums and is exact in the case when $M=o_{L}$. So the complex is exact whenever $M$ is a finitely generated free $o_{L}$-module. If $M$ also happens to be
an $o_{L}[G]$-module for some group $G$, then the maps in the complex are $o_{L}[G]-$ linear. The result follows when we set $M=o_{n}$, an $o_{L}\left[\Gamma / \Gamma_{n}\right]$-module which is free of finite rank as an $o_{L}$-module.

We now pass to the limit as $n \rightarrow \infty$.
Definition 5.2.4. Recall the Iwasawa algebras $\Lambda(\Gamma)=\lim _{幺} o_{L}\left[\Gamma / \Gamma_{n}\right]$ and $\Omega(\Gamma)=\lim _{\leftrightarrows} k_{L}\left[\Gamma / \Gamma_{n}\right]$.
(1) $o_{\infty}:=\operatorname{colim} o_{n}$, an $o_{L}[\Gamma]$-module.
(2) $o_{\infty}^{*}:=\lim _{\rightleftarrows} o_{n}^{*}$, a $\Lambda(\Gamma)$-module.
(3) $k_{\infty}:=\operatorname{colim} k_{n}$, a $k_{L}[\Gamma]$-module.
(4) $k_{\infty}^{\vee}:=\lim _{\leftarrow} k_{n}^{\vee}$, an $\Omega(\Gamma)$-module.

Lemma 5.2.5. There is a short exact sequence of $\Lambda(\Gamma)$-modules

$$
0 \rightarrow o_{\infty}^{*} \xrightarrow{\pi} o_{\infty}^{*} \rightarrow k_{\infty}^{\vee} \rightarrow 0 .
$$

Proof. The short exact sequences from Lemma 5.2.3 are compatible with variation in $n$, in other words we get a short exact sequence of towers of $\Lambda(\Gamma)$ modules. Applying the inverse limit functor gives a long exact sequence

$$
0 \rightarrow o_{\infty}^{*} \xrightarrow{\pi} o_{\infty}^{*} \rightarrow k_{\infty}^{\vee} \rightarrow{\underset{\varliminf}{\lim _{\leftrightarrows}}}^{(1)} o_{n}^{*} .
$$

The $\varliminf_{\mathrm{im}}{ }^{(1)}$ term on the right vanishes in view of Remark 5.2.2(2), whence the result.

Remark 5.2.2(2) also implies that the natural maps $o_{\infty}^{*} \rightarrow o_{n}^{*}$ are surjective.
Proposition 5.2.6. The $\Lambda(\Gamma)$-modules $o_{\infty}$ and $o_{\infty}^{*}$ are faithful.
Proof. Suppose $\xi \in \Lambda(\Gamma)$ kills $o_{\infty}$. Then its image $\xi_{n} \in o\left[\Gamma / \Gamma_{n}\right]$ kills $o_{n}$. Therefore $\xi_{n} \in L\left[\Gamma / \Gamma_{n}\right]$ kills $L_{n}=o_{n} \otimes_{o_{L}} L$. But $L_{n}$ is a free $L\left[\Gamma / \Gamma_{n}\right]$-module of rank 1 by the Normal Basis Theorem. So, $\xi_{n}=0$ for all $n \geq 0$ and therefore $\xi=0$ as well.

Suppose now $\xi \in \Lambda(\Gamma)$ kills $o_{\infty}^{*}$. Then $\xi$ kills each the quotients $o_{n}^{*}$ of $o_{\infty}^{*}$. But the action of $\Lambda(\Gamma)$ on $o_{n}^{*}$ factors through $o_{L}\left[\Gamma / \Gamma_{n}\right]$, so the image $\xi_{n}$ of $\xi$ in $o_{L}\left[\Gamma / \Gamma_{n}\right]$ kills $o_{n}^{*}$. Since $\xi_{n}$ also kills $o_{n} \cong\left(o_{n}^{*}\right)^{*}$, we deduce from the above that $\xi_{n}=0$ for all $n$. Hence $\xi=0$.

Proposition 5.2.7. Suppose that $p \nmid\left|\Gamma / \Gamma_{1}\right|$. Then $k_{1}^{\vee}$ is a free $k_{L}\left[\Gamma / \Gamma_{1}\right]$ module of rank 1.

Proof. The field extension $L_{1} / L$ is tamely ramified by our assumption on $\left|\Gamma / \Gamma_{1}\right|$. Now it follows from Noether's Theorem on rings of integers in tamely ramified extensions that $o_{1}$ is a free $o_{L}\left[\Gamma / \Gamma_{1}\right]$-module of rank one - see, e.g. [33, Proposition 2.1]. Hence $o_{1} / \pi o_{1}$ is a free $k_{L}\left[\Gamma / \Gamma_{1}\right]$-module of rank one, and we can apply Lemma 5.2.3 to conclude.

Lemma 5.2.8. Suppose that $\Gamma$ is a p-adic Lie group. Let $M=\lim _{\gtrless} M_{n}$ be an inverse limit of a tower of $\Omega(\Gamma)$-modules, where each $M_{n}$ is finite dimensional over $k_{L}$. Then the natural map on $\Gamma$-coinvariants

$$
M_{\Gamma} \rightarrow \varliminf_{\check{L i m}}^{\lim _{n}}\left(M_{n}\right)_{\Gamma}
$$

is an isomorphism.
Proof. The Iwasawa algebra $\Omega(\Gamma)$ is Noetherian, so its augmentation ideal $J=(\Gamma-1) \Omega(\Gamma)$ is finitely generated. Let $u_{1}, \cdots, u_{r} \in J$ be generators and let $N$ be an $\Omega(\Gamma)$-module; then

$$
N_{\Gamma}=N /(\Gamma-1) \cdot N=N / J N=N /\left(u_{1} N+\cdots+u_{r} N\right)
$$

In other words, we have the short exact sequence of $k_{L}$-vector spaces

$$
\begin{equation*}
N^{r} \stackrel{\left(u_{1}, \cdots, u_{r}\right)}{\longrightarrow} N \rightarrow N_{\Gamma} \rightarrow 0 \tag{18}
\end{equation*}
$$

Applying this to each $M_{n}$, we obtain an exact sequence of towers of $\Omega(\Gamma)$ modules

$$
M_{n}^{r} \xrightarrow{\left(u_{1}, \cdots, u_{r}\right)} M_{n} \rightarrow\left(M_{n}\right)_{\Gamma} \rightarrow 0
$$

where each term is a finite dimensional $k_{L}$-vector space. The inverse limit functor is exact on such towers, since they all satisfy the Mittag-Leffler condition. So passing to the inverse limit we obtain the exact sequence of $k_{L}$-vector spaces

$$
M^{r} \xrightarrow{\left(u_{1}, \cdots, u_{r}\right)} M \rightarrow \underset{\lim _{\longleftrightarrow}}{\longrightarrow}\left(M_{n}\right)_{\Gamma} \rightarrow 0 .
$$

Comparing this with (18) applied with $N=M$ gives the result.
Theorem 5.2.9. Suppose that

- $\Gamma$ is abelian,
- $p \nmid\left|\Gamma / \Gamma_{1}\right|$,
- $\Gamma_{1}$ is a torsionfree pro-p group of finite rank.

Then $o_{\infty}^{*}$ is a free $\Lambda(\Gamma)$-module of rank 1 if and only if the map $k_{1} \rightarrow k_{\infty}^{\Gamma_{1}}$ is an isomorphism.

Proof. $(\Leftarrow)$ Note that the connecting maps $k_{n} \rightarrow k_{n+1}$ in the colimit $k_{\infty}:=$ colim $k_{n}$ are injective: if $x+\pi o_{n} \in k_{n}$ maps to zero in $k_{n+1}$ then there is $y \in o_{n+1}$ such that $x=\pi y$; but then $y \in L_{n} \cap o_{n+1}=o_{n}$ and hence $x=$ $\pi y \in \pi o_{n}$. Under our hypothesis that $k_{1} \rightarrow k_{\infty}^{\Gamma_{1}}$ is an isomorphism, it follows that for each $n \geq 1$, the map $k_{n}^{\Gamma_{1}} \rightarrow k_{n+1}^{\Gamma_{1}}$ is an isomorphism. Applying the $(-)^{\vee}=\operatorname{Hom}_{k_{L}}\left(-, k_{L}\right)$ functor, we deduce that for each $n \geq 1$, the map on $\Gamma_{1}$-coinvariants

$$
\left(k_{n+1}^{\vee}\right)_{\Gamma_{1}} \rightarrow\left(k_{n}^{\vee}\right)_{\Gamma_{1}}
$$

is an isomorphism. Now, Lemma 5.2.8 tells us that

$$
\left(k_{\infty}^{\vee}\right)_{\Gamma_{1}} \cong \lim _{\check{ }}\left(k_{n}^{\vee}\right)_{\Gamma_{1}} .
$$

Since the maps in the tower of $\Gamma_{1}$-coinvariants are all isomorphisms, we conclude that the natural map of $k\left[\Gamma / \Gamma_{1}\right]$-modules

$$
\left(k_{\infty}^{\vee}\right)_{\Gamma_{1}} \rightarrow k_{1}^{\vee}
$$

must be an isomorphism. Now $k_{1}^{\vee}$ is a cyclic $k_{L}\left[\Gamma / \Gamma_{1}\right]$-module by Proposition 5.2 .7 and the ideal $J \Omega(\Gamma)$ generated by the augmentation ideal $J$ of $\Omega\left(\Gamma_{1}\right)$ is topologically nilpotent in the sense that $J^{n} \rightarrow 0$ as $n \rightarrow \infty$, because $\Gamma_{1}$ is assumed to be pro- $p$. In this situation we can apply the Nakayama Lemma for compact $\Lambda$-modules - see $\left[3\right.$, Corollary to Theorem 3] - to deduce that $k_{\infty}^{\vee}$ is a cyclic $\Omega(\Gamma)$-module: any lift of a $k_{L}\left[\Gamma / \Gamma_{1}\right]$-module generator for $k_{1}^{\vee}$ to $k_{\infty}^{\vee}$ will generate it as an $\Omega(\Gamma)$-module.

Now $o_{\infty}^{*} / \pi o_{\infty}^{*} \cong k_{\infty}^{\vee}$ by Lemma 5.2.5. The $\Lambda(\Gamma)$-module $o_{\infty}^{*}$ is profinite and $\pi^{n} \rightarrow 0$ as $n \rightarrow \infty$ in $\Lambda(\Gamma)$, so applying the Nakayama Lemma again, we conclude that $o_{\infty}^{*}$ is a cyclic $\Lambda(\Gamma)$-module.

Since $o_{\infty}^{*}$ is a faithful $\Lambda(\Gamma)$-module by Proposition 5.2.6 and since $\Gamma$ is abelian, we deduce that $o_{\infty}^{*}$ must be a free $\Lambda(\Gamma)$-module of rank 1 .
$(\Rightarrow)$ We reverse the argument above. Assume $o_{\infty}^{*}$ is a free $\Lambda(\Gamma)$-module of rank 1. Then Lemma 5.2 .5 implies that $k_{\infty}^{\vee}$ is a free $\Omega(\Gamma)$-module of rank 1. Hence $\left(k_{\infty}^{\vee}\right)_{\Gamma_{1}}$ is a free $k\left[\Gamma / \Gamma_{1}\right]$-module of rank 1. By Lemma 5.2 .8 we have $\left(k_{\infty}^{\vee}\right)_{\Gamma_{1}} \cong \lim _{\rightleftarrows}\left(k_{n}^{\vee}\right)_{\Gamma_{1}}$ and the connecting maps in the tower $\left(k_{n}^{\vee}\right)_{\Gamma_{1}}$ are surjective, with the bottom term being $\left(k_{1}^{\vee}\right)_{\Gamma_{1}}=k_{1}^{\vee}$. Since this is a free $k_{L}\left[\Gamma / \Gamma_{1}\right]$-module of rank 1 by Proposition 5.2.7, the natural map $\left(k_{\infty}^{\vee}\right)_{\Gamma_{1}} \rightarrow k_{1}^{\vee}$ from the inverse limit to the bottom term is a surjection between two free $k_{L}\left[\Gamma / \Gamma_{1}\right]$-modules of rank 1. So it is also an isomorphism. Dualising shows that $k_{1} \rightarrow k_{\infty}^{\Gamma_{1}}$ is an isomorphism as well.

Lemma 5.2.10. In the situation of Proposition 5.2.9, suppose that $o_{\infty}^{*}$ is a free $\Lambda(\Gamma)$-module of rank 1 . Then $L_{n} / L$ is tamely ramified for all $n \geq 1$.

Proof. Consider the $\Gamma_{n}$-coinvariants of $o_{\infty}^{*}$. These coinvariant must be a free rank $1 o_{L}\left[\Gamma / \Gamma_{n}\right]$-module by assumption. On the other hand, by construction, there's a surjective $o_{L}\left[\Gamma / \Gamma_{n}\right]$-linear map

$$
\left(o_{\infty}^{*}\right)_{\Gamma_{n}} \rightarrow o_{n}^{*}
$$

(see the remark just before Proposition 5.2.6). Both sides are free $o_{L}$-modules of rank $\left[L_{n}: L\right]$, so this surjective map must actually be an isomorphism by the rank-nullity theorem. So, $o_{n}^{*}$ is a free rank $1 o_{L}\left[\Gamma / \Gamma_{n}\right]$-module. But then using, for example [2, Lemma 5.4], we see that

$$
o_{n}=\operatorname{Hom}_{o_{L}}\left(o_{n}^{*}, o_{L}\right)=\operatorname{Hom}_{o_{L}\left[\Gamma / \Gamma_{n}\right]}\left(o_{n}^{*}, o_{L}\left[\Gamma / \Gamma_{n}\right]\right)
$$

must also be a free rank $1 o_{L}\left[\Gamma / \Gamma_{n}\right]$-module. In other words, $o_{n}$ has an integral normal basis, so by [33, Proposition 2.1] $L_{n} / L$ must be tamely ramified.

The following result, which may be of independent interest, shows that the hypothesis that the action map $\rho: \Omega(\Gamma) \rightarrow \operatorname{End}_{\Omega(\Gamma)}\left(k_{\infty}^{\vee}\right)$ is an isomorphism has strong implications about ramification behaviour in the tower $L_{\infty} / L$.

Lemma 5.2.11. Suppose $\Gamma$ is a torsionfree abelian pro-p group of finite rank, and that the action map $\rho: \Omega(\Gamma) \rightarrow \operatorname{End}_{\Omega(\Gamma)}\left(k_{\infty}^{\vee}\right)$ is an isomorphism. Assume that $\Gamma_{1}=\Gamma$. Then $L_{n} / L$ is tamely ramified for all $n \geq 1$.
Proof. Let $a \in k_{\infty}^{\Gamma_{1}}$ and consider the multiplication-by- $a$ map $\ell_{a}: k_{\infty} \rightarrow k_{\infty}$. Since $a$ is fixed by $\Gamma=\Gamma_{1}$, this map is $\Omega(\Gamma)$-linear. By our assumption on $\rho$, we can find some $b \in \Omega(\Gamma)$ such that $\rho(b)=a$. Now $a$ is algebraic over $k_{L}$ and $\rho$ is injective by assumption, so $b \in \Omega(\Gamma)$ must be algebraic over $k_{L}$ as well. Since $\Gamma=\Gamma_{1}$, the mod- $p$ Iwasawa algebra $\Omega(\Gamma)$ is a power series ring over $k_{L}$ in finitely many variables. The only elements of such a power series ring that are algebraic over $k_{L}$ are constants. Hence $b \in k_{L}$ and so $a \in k_{L}=k_{1}$ since $\Gamma=\Gamma_{1}$. Hence $k_{\infty}^{\Gamma_{1}}=k_{1}$. Now the result follows from Theorem 5.2.9 and Lemma 5.2.10.

Returning to the setting of $\S 1.7$, we have the following conclusion.
Corollary 5.2.12. Suppose that $L=\mathbb{Q}_{p^{2}}$ and $\pi=p$, and let $\mathcal{G}$ be the Lubin-Tate formal group attached to $\pi$. Let $\Gamma_{L}^{L T}=\operatorname{Gal}\left(L\left(\mathcal{G}\left[p^{\infty}\right]\right) / L\right)$. Then $o_{L} \llbracket Z \rrbracket^{\psi_{q}=0}$ is not a free $o_{L} \llbracket \Gamma_{L}^{\mathrm{LT}} \rrbracket$-module of rank 1 .
Proof. It is well known that $L_{n} / L$ is not tamely ramified for any $n \geq 2$. Hence $o_{\infty}^{*}$ is not a free $\Lambda\left(\Gamma_{L}^{L T}\right)$-module of rank 1 by Lemma 5.2.10. Since $\mathcal{G}$ is selfdual, the tower $L_{\infty} / L$ coincides with the one defined at Definition 2.7.1(1). The result now follows from Theorem 1.7.1.
5.3. The operator $\psi$ and the span of the $P_{n}$. We now turn to some consequences of the Katz isomorphism for the span of the $P_{n}$, where $P_{n}$ is the element of $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$ given by $a \mapsto P_{n}(a \cdot \Omega)$. The Katz map $\mathcal{K}^{*}$ : $\operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), S\right) \rightarrow S \llbracket Z \rrbracket^{\psi_{q}-\text { int }}$ is then given by $\mu \mapsto \sum_{n \geq 0} \mu\left(P_{n}\right) Z^{n}$.
Proposition 5.3.1. The L-span of the $P_{n}$ is dense in the L-Banach space $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$.
Proof. Let $W$ denote the closure of the $L$-span of the $P_{n}$ in $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$. If $W \neq \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$, then it has a closed complement in $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ and we can find a measure $\mu \neq 0$ that is zero on $W$ (and hence on all of the $P_{n}$ ). This is a contradiction.

Remark 5.3.2. There is another proof of this result. Indeed, locally analytic functions are dense in $\mathcal{C}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ and for locally analytic functions, we have the generalized Mahler expansion of [28, Theorem 4.7]. So it is enough to prove that locally analytic and Gal continuous functions are dense in $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$.

A Gal-continuous function is determined by $\left(f\left(p^{n}\right)\right)_{n=0}^{\infty}$ where each $f\left(p^{n}\right) \in$ $L_{\infty}$ and $f(0) \in L$ and $f\left(p^{n}\right) \rightarrow f(0)$ (see also $\S \S 3.3-3.4$ ). We can approximate each $f\left(p^{n}\right)$ by an element of $L_{\infty}$ and this way, we can show that Gal-continuous locally constant functions are dense in the Gal-continuous functions. More precisely, given a sequence $\left\{f_{n}\right\}$ as above and some $k \geq 0$, we have $f_{n}-f_{\infty} \in$ $p^{k} o_{\mathbb{C}_{p}}$ for all $n \geq n(k)$, so we replace these $f_{n}$ by $f_{\infty}$, and approximate the others to within $p^{-k}$.

We now choose a coordinate $X$ on LT such that $[p]_{\mathrm{LT}}(X)=p X+X^{q}$. The polynomials $P_{i}$ depend on the choice of coordinate. However, the $o_{L^{-}}$ module $U_{n}=\oplus_{i=0}^{n} o_{L} \cdot P_{i}$ is independent of the coordinate. Given this choice of coordinate, we have formulas and estimates for $\psi_{q}$ in [15, $\left.\S 2 \mathrm{~A}\right]$.
Lemma 5.3.3. If $k \geq 1$, then $\psi_{q}\left(X^{k}\right) \in L[X]_{k-1}$.
Proof. See [15, Proposition 2.2].
Let $c^{0}(A)$ denote the set of sequences $\left\{c_{n}\right\}_{n \geq 0}$ with $c_{n} \in A$ and $c_{n} \rightarrow 0$ (with $A=o_{L}$ or $L$ ).
Corollary 5.3.4. The map $c^{0}\left(o_{L}\right) \rightarrow \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$ given by $\left\{c_{i}\right\}_{i \geq 0} \mapsto \sum c_{i} P_{i}$ is injective, as well as the same map $c^{0}(L) \rightarrow \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$.
Proof. Lemma 5.3.3 implies that for all $k \geq 0$, there exists $n=n(k)$ such that $p^{n} X^{k} \in o_{L} \llbracket X \rrbracket \psi_{q}$-int. Let $\mu$ be the corresponding measure. We have $\mu\left(\sum_{i \geq 0} c_{i} P_{i}\right)=p^{n} c_{k}$ hence if $\sum_{i \geq 0} c_{i} P_{i}=0$, then $c_{k}=0$. The second assertion follows from the first.

Lemma 5.3.5. If $k \geq 1$, then $\psi_{q}\left(p^{k} \cdot o_{L}[X]_{q^{k}}\right) \subset p^{k-1} \cdot o_{L}[X]_{q^{k-1}}$.
Proof. This follows from [15, Proposition 2.2].
Let $H_{n} \subset L[\Omega]$ denote the set of $P(\Omega)$ such that $\operatorname{deg} P \leq n$ and $P(a \Omega) \in o_{\mathbb{C}_{p}}$ for all $a \in o_{L}$. Obviously, $U_{n}=\oplus_{i=0}^{n} o_{L} \cdot P_{i}(\Omega) \subset H_{n}$. Let $\mu_{i}: \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right) \rightarrow$ $L$ be the measure corresponding to $X^{i}$, so that $\mu_{i}\left(P_{j}\right)=\delta_{i j}$.
Proposition 5.3.6. If $Q(\Omega)=\sum_{i=0}^{n} c_{i} P_{i}(\Omega) \in H_{n}$, then $c_{i} \in p^{-m} o_{L}$ if $i \leq$ $q^{m}$.
Proof. We have $Q(\Omega) \in \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$. By Lemma 5.3.5, $p^{m} X^{i} \in o_{L} \llbracket X \rrbracket^{\psi_{q} \text {-int }}$ if $i \leq q^{m}$, and hence $p^{m} \mu_{i} \in \operatorname{Hom}_{o_{L}}\left(\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right), o_{L}\right)$ for all $0 \leq i \leq q^{m}$. Hence $p^{m} c_{i} \in o_{L}$.
Corollary 5.3.7. We have $H_{q^{k}} \subset p^{-k} U_{q^{k}}$.
Let $\psi_{p}=p \cdot \psi_{q}$ so that $\psi_{p}\left(o_{L} \llbracket X \rrbracket\right) \subset o_{L} \llbracket X \rrbracket$.
Lemma 5.3.8. $\psi_{p}\left(X^{q k+(q-1)}\right)=X^{k} \bmod p$ and $\psi_{p}\left(X^{m}\right)=0 \bmod p$ if $m \neq$ $-1 \bmod q$.

Proof. This follows from [15, Proposition 2.2].
Corollary 5.3.9. The map $c^{0}(L) \rightarrow \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ is not surjective.
Proof. By Corollary 5.3.4, it is injective. If it is a bijection, then the continuous dual of $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$ is naturally isomorphic to $o_{L} \llbracket X \rrbracket[1 / p]$ via the map $\mu \mapsto$ $\sum_{n \geq 0} \mu\left(P_{n}\right) X^{n}$. However by the Katz isomorphism, the image of this map is $o_{L} \llbracket \bar{X} \rrbracket^{\psi_{q} \text {-int }}[1 / p \rrbracket$.

Take $f(X)=1+X^{q-1}+X^{q^{2}-1}+\cdots$. Lemma 5.3.8 implies that $\psi_{p}(f)=$ $f \bmod p$ and hence $\psi_{p}^{n}(f)=f \bmod p$. We therefore have $\psi_{q}^{n}(f) \in p^{-n} f+$ $p^{-(n-1)} o_{L} \llbracket X \rrbracket$ for all $n \geq 1$, so that $f(X)$ is not in $o_{L} \llbracket X \rrbracket{ }^{\psi_{q}-\text { int }}[1 / p]$. Hence $o_{L} \llbracket X \rrbracket[1 / p] \neq o_{L} \llbracket X \rrbracket^{\psi_{q}-\text { int }}[1 / p]$.

In order to say more using Katz' result, we need to produce more elements of $o_{L} \llbracket X \rrbracket \psi_{q}$-int . There is $o_{L} \llbracket X \rrbracket \psi_{q}=0$, which contains $X^{i}$ for $1 \leq i \leq q-2$ and $p X^{q-1}+(q-1)$ and hence $\left(\oplus_{i=1}^{q-2} X^{i} \cdot \varphi_{q}\left(o_{L} \llbracket X \rrbracket\right)\right) \oplus\left(p X^{q-1}+(q-1)\right) \cdot \varphi_{q}\left(o_{L} \llbracket X \rrbracket\right)$. If $f_{n}(X) \in\left(X \cdot o_{L} \llbracket X \rrbracket\right)^{\psi_{q} \text {-int }}$ and the $b_{n}$ are in $o_{L}$, then $\sum_{n \geq 0} b_{n} \varphi_{q}^{n}\left(f_{n}\right) \in$ $o_{L} \llbracket X \rrbracket^{\psi_{q} \text {-int }}$ as well (the sum converges for the weak topology, and $\psi_{q}$ is continuous for that topology). For example, if $f(X) \in\left(X \cdot o_{L} \llbracket X \rrbracket\right)^{\psi_{q}=0}$, then $\sum_{n \geq 0} \varphi_{q}^{n}(f) \in o_{L} \llbracket X \rrbracket^{\psi_{q}=1}$.
Remark 5.3.10. We have
(1) $\psi_{q}\left(X^{i}\right)=0$ if $1 \leq i \leq q-2$ and $q+1 \leq i \leq 2 q-3$ and $2 q+1 \leq i \leq 3 q-4$
(2) $\psi_{q}(1)=1$ and $\psi_{q}\left(X^{q-1}\right)=(1-q) / p$ and $\psi_{q}\left(X^{q}\right)=X$
(3) $\psi_{q}\left(X^{2 q-2}\right)=q-1$ and $\psi_{q}\left(X^{2 q-1}\right)=X(1 / p-2 p)$ and $\psi_{q}\left(X^{2 q}\right)=X^{2}$
(4) More generally, $\psi_{q}\left(X^{k}\right)=X \psi_{q}\left(X^{k-q}\right)-p \psi_{q}\left(X^{k+1-q}\right)$

Lemma 5.3.11. We have $p^{k} X^{q^{k}-1} \in o_{L} \llbracket X \rrbracket^{\psi_{q} \text {-int }}$, but not $p^{k-1} X^{q^{k}-1}$.
Proof. Recall that $\psi_{q}\left(X^{q-1}\right)=(1-q) / p$. This implies that $\psi_{q}(1 / X)=$ $\psi_{q}\left(\left(X^{q-1}+p\right) / \varphi_{q}(X)\right)=1 / p X$. If $k \geq 1$, then

$$
\binom{q^{k-1}}{i} \cdot p^{i}=\binom{q^{k-1}-1}{i-1} \cdot q^{k-1} p^{i} / i \in p^{k} o_{L}
$$

This implies that $\varphi_{q}\left(X^{q^{k-1}}\right) \in X^{q^{k}}+p^{k} X o_{L}[X]_{q^{k}-1}$. By Lemma 5.3.5, we have
$\psi_{q}\left(X^{q^{k}-1}\right)=\psi_{q}\left(\frac{\varphi_{q}\left(X^{q^{k-1}}\right)+X^{q^{k}}-\varphi_{q}\left(X^{q^{k-1}}\right)}{X}\right) \in \frac{X^{q^{k-1}-1}}{p}+o_{L} \llbracket X \rrbracket^{\psi_{q}-\mathrm{int}}$.
This implies the Lemma by induction on $k$.
Corollary 5.3.12. There is an $h \in H$ in which the coefficient of $P_{q^{k}-1}$ is in $p^{-k} o_{L}^{\times}$.
Proof. Let $c_{q^{k}-1} \in \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)^{*}$ be the linear form corresponding to $X^{q^{k}-1}$. There is an $f \in \mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, o_{\mathbb{C}_{p}}\right)$ such that $c_{q^{k}-1}(f) \in p^{-k} o_{L}^{\times}$(if it was in $p^{1-k} o_{L}$ for all $f$, then $p^{k-1} c_{q^{k}-1}$ would be an integral linear form, and we'd have $p^{k-1} X^{q^{k}-1} \in o_{L} \llbracket X \rrbracket^{\psi_{q}-\text { int }}$. This is not the case by Lemma 5.3.11). By Corollary 5.3.1, the $L$-span of the $P_{n}$ is dense in $\mathcal{C}_{\text {Gal }}^{0}\left(o_{L}, \mathbb{C}_{p}\right)$. Therefore there is an $h \in H$ such that $\|f-h\| \leq p^{-1}$. We then have $c_{q^{k}-1}(h) \in p^{-k} o_{L}^{\times}$.

## 6. Other criteria

We indicate how to prove Theorems 1.8.1 and 1.8.2.
6.1. The Lubin-Tate derivative. As we said in the Introduction, Theorem 1.8.1 follows from Theorem 1.4.1 and Proposition 6.1.2 below.

Lemma 6.1.1. The sum $\sum_{[p](\omega)=0} \omega^{n}$ is $q$ if $n=0$, it is 0 if $(q-1) \nmid n$, and it is $(q-1)(-p)^{k}$ if $n=(q-1) k$ with $k \geq 1$.

Proof. Since $[p](T)=p T+T^{q}$, the sum is over 0 and the roots of $T^{q-1}=-p$. If $\lambda$ is one of the roots, the set of all the roots is $\{\eta \lambda\}_{\eta^{q-1}=1}$. The result follows (for $n=0$ it is a convention).

Proposition 6.1.2. Assume that $L=\mathbb{Q}_{p^{2}}$ and that $\pi=p$. Let $\lambda=\Omega^{q-1} / p(q-$ $1)!\in o_{\mathbb{C}_{p}}^{\times}$. If $f(Z) \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket$, then $\varphi \psi_{q}(f)-\lambda \cdot D^{q-1}(f) \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket$.

Proof. Recall from [20, p. 667] that $f(Z \oplus Y)=\sum_{n \geq 0} Y^{n} P_{n}(\partial) f(Z)$. We have $\varphi \psi_{q}(f)(Z)=1 / q \cdot \sum_{[p](\omega)=0} f(Z \oplus \omega)$, so that

$$
\varphi \psi_{q}(f)(Z)=\frac{1}{q} \sum_{[p](\omega)=0} \sum_{n \geq 0} \omega^{n} P_{n}(\partial) f(Z)=\frac{1}{q} \sum_{n \geq 0}\left(\sum_{[p](\omega)=0} \omega^{n}\right) P_{n}(\partial) f(Z)
$$

By Lemma 6.1.1, the $\sum \omega^{n}$ for $n$ not divisible by $q-1$ are zero, and the $\sum \omega^{n}$ for $n=(q-1) k$ are divisible by $q$ except when $k=1$. Hence

$$
\varphi \psi_{q}(f)-\frac{1}{q}(q-1)(-p) P_{q-1}(\partial)(f) \in o_{\mathbb{C}_{p}} \llbracket Z \rrbracket .
$$

The proposition now follows from the fact that

$$
P_{q-1}(\partial)=\frac{\partial^{q-1}}{(q-1)!}=p D^{q-1} \cdot \frac{\Omega^{q-1}}{p(q-1)!}=p D^{q-1} \cdot \lambda
$$

6.2. Changing the base field. We now turn to Theorem 1.8.2. If $K$ is a subfield of $L$, we also have a character variety $\mathfrak{X}$ for $K$; write $\mathfrak{X}_{K}$ and $\mathfrak{X}_{L}$. An $L$-analytic character $\eta: o_{L} \rightarrow \mathbb{C}_{p}^{\times}$can be restricted to $o_{K}$, and it is then $K$-analytic. This gives a rigid analytic map $\mathfrak{X}_{L} \rightarrow \mathfrak{X}_{K}$. This map in turn gives rise to a map $\operatorname{res}_{L / K}: \mathcal{O}_{\mathbb{C}_{p}}\left(\mathfrak{X}_{K}\right) \rightarrow \mathcal{O}_{\mathbb{C}_{p}}\left(\mathfrak{X}_{L}\right)$, which sends bounded functions to bounded functions, and $\mathcal{O}_{M}\left(\mathfrak{X}_{K}\right)$ to $\mathcal{O}_{M}\left(\mathfrak{X}_{L}\right)$ for all closed subfields $L \subset$ $M \subset \mathbb{C}_{p}$.
Lemma 6.2.1. On bounded functions, $\operatorname{res}_{L / K}: \mathcal{O}_{\mathbb{C}_{p}}^{b}\left(\mathfrak{X}_{K}\right) \rightarrow \mathcal{O}_{\mathbb{C}_{p}}^{b}\left(\mathfrak{X}_{L}\right)$ is injective.

Proof. Suppose that $f \in \mathcal{O}_{\mathbb{C}_{p}}^{b}\left(\mathfrak{X}_{K}\right)$ is zero on the restriction to $o_{K}$ of every $L$-analytic character of $o_{L}$. Since $o_{K}$ is a direct summand of $o_{L}$, every torsion character of $o_{K}$ extends to a torsion character of $o_{L}$. Hence $f$ is zero on all torsion characters of $o_{K}$. This implies that $f=0$ as $f$ is bounded.

If $\mu$ is a distribution on $o_{K}$, we define a distribution $\operatorname{res}_{L / K}(\mu)$ on $o_{L}$ as follows: if $f \in \mathcal{C}^{a n}\left(o_{L}\right)$, we let $\operatorname{res}_{L / K}(\mu)(f)=\mu\left(\left.f\right|_{O_{K}}\right)$. This is compatible with the above map if we view elements of $\mathcal{O}_{\mathbb{C}_{p}}(\mathfrak{X})$ as distributions.
Lemma 6.2.2. If $\mu$ is a distribution on $o_{K}$, whose image under $\operatorname{res}_{L / K}(\mu)$ is a measure on $o_{L}$, then there exists a measure $\tilde{\mu}$ on $o_{K}$ such that $\mu=\tilde{\mu}$ on $\mathrm{LC}\left(o_{K}\right)$.

Proof. Let $f$ be a locally constant function on $o_{K}$. Since $o_{K}$ is a direct summand in $o_{L}$, we can extend $f$ to a locally constant function $\tilde{f}$ on $o_{L}$, in a way that the sup norm of $\tilde{f}$ on $o_{L}$ is the sup norm of $f$ on $o_{K}$. Since $\operatorname{res}_{L / K}(\mu)$ is a
measure, there exists $C$ such that $\left\|\operatorname{res}_{L / K}(\mu)(g)\right\|_{o_{L}} \leq C \cdot\|g\|_{o_{L}}$ for all locally constant functions $g$ on $o_{L}$. We then have

$$
\|\mu(f)\|_{o_{K}}=\left\|\operatorname{res}_{L / K}(\mu)(\tilde{f})\right\|_{o_{L}} \leq C \cdot\|\tilde{f}\|_{o_{L}}=C \cdot\|f\|_{o_{K}}
$$

We can now let $\tilde{\mu}(f)=\mu(f)$ for any $f \in \operatorname{LC}\left(o_{K}\right)$. The above estimate shows that $\tilde{\mu}$ extends continuously to $\mathcal{C}^{0}\left(o_{K}\right)$.
Proposition 6.2.3. If $\mathcal{O}_{L}^{b}\left(\mathfrak{X}_{L}\right)=L \otimes_{o_{L}} \Lambda\left(o_{L}\right)$, then $\mathcal{O}_{L}^{b}\left(\mathfrak{X}_{K}\right)=L \otimes_{o_{K}} \Lambda\left(o_{K}\right)$.
Proof. If $\mu \in \mathcal{O}_{L}^{b}\left(\mathfrak{X}_{K}\right)$, then $\mu$ can be seen as a distribution on $o_{K}$, and it gives rise via $\operatorname{res}_{L / K}$ to an element of $L \otimes_{o_{L}} \Lambda\left(o_{L}\right)$. By Lemma 6.2.2, there is a measure $\tilde{\mu}$ on $o_{K}$ such that $\mu=\tilde{\mu}$ on $\mathrm{LC}\left(o_{K}\right)$. The image of the distribution $\mu-\tilde{\mu}$ under $\operatorname{res}_{L / K}$ belongs to $L \otimes_{o_{L}} \Lambda\left(o_{L}\right)$ and is zero on locally constant functions, hence $\operatorname{res}_{L / K}(\mu-\tilde{\mu})=0$. By Lemma $6.2 .1, \mu=\tilde{\mu}$ and hence $\mu$ is a measure on $o_{K}$.

Theorem 6.2.4. If $L / K$ is finite and if $\Lambda_{L}\left(\mathfrak{X}_{L}\right)=o_{L} \llbracket o_{L} \rrbracket$, then $\Lambda_{K}\left(\mathfrak{X}_{K}\right)=$ $o_{K} \llbracket o_{K} \rrbracket$.

Appendix A. An algorithm for whether the $\sigma_{i, j}$ 's Span $\operatorname{Int}\left(o_{L}, o_{L}\right)$

## Dragoș Crișan and Jinguie Yang

Acknowledgements. The authors took part in an Oxford summer project together with Shashidhara Balla, Jonathan Medcalf and William Whitehead. Financial support from the LMS, Brasenose College, University College, Merton College and the Mathematical Institute, Oxford is gratefully acknowledged.
A.1. Introduction. Let $\mathbb{Q}_{p} \subseteq L \subsetneq \mathbb{C}_{p}$ be a field of finite degree $d$ over $\mathbb{Q}_{p}, o_{L}$ the ring of integers of $L, \pi \in o_{L}$ a fixed prime element, and $q:=\left|o_{L} / \pi_{L} o_{L}\right|$ the dimension of the residue field. For an $o_{L}$-submodule $S$ of $L[Y]$ and an integer $n$, let $S_{n}=\{f \in S: \operatorname{deg}(f)<n\}$.

Recall that the polynomials $P_{n}(Y)$ are defined by

$$
\exp \left(Y \cdot \log _{\mathrm{LT}}(Z)\right)=\sum_{n=0}^{\infty} P_{n}(Y) Z^{n}
$$

We choose the coordinate $Z$ such that $\log _{\mathrm{LT}}(Z)=\sum_{k=0}^{\infty} \pi^{-k} Z^{q^{k}}$.
Define the upper-triangular matrix $\left(\sigma_{i, j}\right)_{i, j \geq 0}$ with entries in $L[Y]$ by

$$
P_{j}(Y s)=\sum_{i=0}^{j} \sigma_{i, j}(Y) P_{i}(s)
$$

By Lemmas 4.3.8 and 4.2.8, we know that $\sigma_{i, j}(Y) \in \operatorname{Int}\left(o_{L}, o_{L}\right)$ and that $\operatorname{deg}\left(\sigma_{i, j}(Y)\right) \leq j$. The question that we consider is whether the $o_{L}$-linear span of $\left\{\sigma_{i, j}(Y): 0 \leq i \leq j\right\}$ equals $\operatorname{Int}\left(o_{L}, o_{L}\right)$. In this write-up we develop an algorithm to check whether $\left(\operatorname{Int}\left(o_{L}, o_{L}\right)\right)_{n}$ is contained in the $o_{L}$-linear span of $\left\{\sigma_{i, j}(Y): 0 \leq i \leq j<N\right\}$ for some fixed $N$, where for convenience we require $q-1 \mid N$.

## A.2. Theory.

A.2.1. Reduction to $\tau_{i, j}^{(a)}$. To ease notation, for a fixed $a \in\{0,1, \ldots, q-2\}$, we denote $\underline{i}=a+(q-1) i$. By Proposition 4.3.9(2), there exist upper-triangular matrices $\tau_{i, j}^{(a)}(Y)$ such that

$$
\begin{equation*}
\sigma_{\underline{i}, \underline{j}}(Y)=Y^{a} \cdot \tau_{i, j}^{(a)}\left(Y^{q-1}\right) \tag{19}
\end{equation*}
$$

Definition A.2.1. For a polynomial $P(x)$, we denote by $\gamma_{n}(P)$ the coefficient of $x^{n}$ in $P$.

Definition A.2.2. Let $M$ be the $o_{L}$-linear span of $\left\{\sigma_{i, j}(Y): 0 \leq i \leq j\right\}$. For a fixed $a$, let $M^{(a)}$ be the $o_{L}$-linear span of $\left\{\sigma_{\underline{i}, \underline{j}}(Y): 0 \leq i \leq j\right\}$. Let $S^{(a)}$ be the $o_{L}$-linear span of $\left\{\tau_{i, j}^{(a)}(Y): 0 \leq i \leq j\right\}$.
Lemma A.2.3. Let $\left(f_{b}^{(a)}\right)_{b \geq 0}$ be a regular basis for $S^{(a)}$ - that is, each $f_{b}^{(a)}$ has degree $b$. Then, $M=\operatorname{Int}\left(o_{L}, o_{L}\right)$ if and only if for all $a \in\{0,1, \ldots q-2\}$ and $b \geq 0$, we have

$$
\nu_{\pi}\left(\gamma_{b}\left(f_{b}^{(a)}\right)\right)=-w_{q}(a+b(q-1))
$$

Proof. For a fixed $a \in\{0,1, \ldots q-2\}$, by (19), we have $\gamma_{s}\left(\sigma_{i, j}(Y)\right)=0$ if $s \not \equiv j$ $(\bmod q-1)$. So, by definition, $M=\bigoplus_{a=0}^{q-2} M^{(a)}$.

We write $S^{(a)}\left(Y^{q-1}\right)=\left\{f\left(Y^{q-1}\right): f \in S^{(a)}\right\}$. Equation (19) shows that

$$
M^{(a)}=Y^{a} \cdot N^{(a)}\left(Y^{q-1}\right)
$$

Having chosen a regular basis $\left(f_{b}^{(a)}\right)_{b \geq 0}$, these give rise to regular bases $\left(f_{b}^{(a)}\left(Y^{q-1}\right)\right)_{b \geq 0}$ for $S^{(a)}\left(Y^{q-1}\right)$.

So, we get regular bases $\left(Y^{a} f_{b}^{(a)}\left(Y^{q-1}\right)\right)_{b \geq 0}$ for $M^{(a)}$ and thus a regular basis $\left\{Y^{a} f_{b}^{(a)}\left(Y^{q-1}\right): a \in\{0,1, \ldots q-2\}, b \geq 0\right\}$ for $M$.

Then, $M=\operatorname{Int}\left(o_{L}, o_{L}\right)$ is equivalent to $\nu_{\pi}\left(\gamma_{a+b(q-1)}\left(Y^{a} f_{b}^{(a)}\left(Y^{q-1}\right)\right)\right)=$ $-w_{q}(a+b(q-1))$, which is equivalent to $\nu_{\pi}\left(\gamma_{b}\left(f_{b}^{(a)}\right)\right)=-w_{q}(a+b(q-1))$.

Let $n=a+b(q-1)$, where $a, b$ are integers, with $a \in\{0,1, \ldots q-2\}$. The proof above shows that a polynomial of degree $n$ with $\pi$-valuation of leading term equal to $-w_{q}(n)$ exists in $M_{N}$ if and only a polynomial of degree $b$ with the same valuation of leading term exists in $S_{N /(q-1)}^{(a)}$. So, the strategy will be to compute regular bases for $S_{N /(q-1)}^{(a)}$.
A.2.2. A formula for $\tau_{i, j}^{(a)}$. One advantage of this approach is that the matrices $\tau_{i, j}^{(a)}(Y)$ can be computed quickly. Recall Definition 4.3.3 (where we merely change notation, calling $m$ by $a$ instead):

Definition A.2.4. For each $j \geq i \geq 0$, let

$$
\begin{aligned}
Q_{a}(i, j) & :=\left\{\mathbf{k} \in \mathbb{N}^{\infty}: \sum_{\ell=0}^{\infty} k_{\ell}=\underline{i}, \sum_{\ell=1}^{\infty} k_{\ell}\left(\frac{q^{\ell}-1}{q-1}\right)=j-i\right\} \\
r_{i, j}^{(a)} & :=\sum_{\mathbf{k} \in Q_{a}(i, j)}\binom{\underline{i}}{k_{0} ; k_{1} ; \ldots} \cdot \pi^{-\sum_{\ell=1}^{\infty} \ell \cdot k_{\ell}}
\end{aligned}
$$

Define the upper triangular matrix $\left(D_{i, j}\right)_{i, j}$ of coefficients as follows:
Definition A.2.5. Let $D_{i, j}=i!\gamma_{i} P_{j}(Y)$.
This does not depend on $a$. From Proposition 4.3.2, we obtain the following recursion formula, valid for $i \geq 1$ :

$$
D_{i, j}=\sum_{r \geq 0} \pi^{-r} D_{i-1, j-q^{r}},
$$

with the initial conditions being $D_{0, j}=\delta_{0, j}$.
Now, by Proposition 4.3.5(2) it follows that $r_{i, j}^{(a)}=D_{\underline{i}, \underline{j}}$. To tie this back to $\tau_{i, j}^{(a)}$, we recall from Definition 4.3.11(3) the notation $\mathcal{D}_{Y}:=\operatorname{diag}\left(1, Y, Y^{2}, \ldots\right)$. Then, Lemma 4.3.12 gives $\tau^{(a)}=\left(r^{(a)}\right)^{-1} \cdot \mathcal{D}_{Y} \cdot r^{(a)}$. This gives a fast algorithm to compute the matrices $\tau^{(a)}$, as the recurrence relation for $D$ allows us to compute $r^{(a)}$ easily.
A.2.3. Gaussian elimination over a (discrete) valuation ring. Let $R$ be a (discrete) valuation ring and let $A$ be an $m \times n$ matrix with entries in $R$. We define notions of elementary row operations and row echelon form over $R$, similarly to the definitions over a field.

Definition A.2.6. Given a matrix $A$ as above, the elementary row operations are as follows.
(1) Swap two rows.
(2) Multiply an entire row by a unit in $R$.
(3) Add an $R$-multiple of a row to another row.

Lemma A.2.7. Performing elementary row operations on a matrix preserves its $R$-row span.

Proof. For each elementary row operation on $A$, we define an $m \times m$ matrix $B$ with entries in $R$ such that the result of applying the elementary row operation on $A$ is $B A$. Observe that in each case, $B$ is invertible, so $B A$ has the same $R$-row span as $A$.

Lemma A.2.8 (Gaussian Elimination). Let $A$ be a matrix as above. Assume that $m \geq n$ and that $A$ has rank $n$. Then, one can perform a sequence of elementary row operations on $A$ to produce an upper-triangular matrix of rank $n$.

Proof. We will exhibit an algorithm that puts $A$ in the required form.
We start with the leftmost column. As $A$ has rank $n$, there is a non-zero entry on column 1. Pick the one with minimal valuation and swap rows, so that the entry on column 0 with minimal valuation is on position ( 0,0 ). Let the new matrix be $B$.

Then, for each row $i \geq 1$, subtract $\frac{b_{i 0}}{b_{00}} \times($ row 0$)$ from row $i$. After all of these operations, the matrix has block form:

$$
\left[\begin{array}{c|c}
b_{00} & * \\
\hline 0 & A^{\prime}
\end{array}\right]
$$

where $*$ denotes some $1 \times(n-1)$ matrix, and $A^{\prime}$ is an $(m-1) \times(n-1)$ matrix. Observe that, as $A$ had rank $n$ and the elementary row operations don't change the rank, $A^{\prime}$ will have rank $n-1$.

Now, we can inductively apply the same procedure to $A^{\prime}$. Observe that all row operations on $A^{\prime}$ extend to row operations on the whole matrix that don't change the block structure (as the corresponding entries in the first column are all 0's). By construction, the end result is an upper-triangular matrix, which has the same rank as the initial matrix $A$.
A.3. Implementation. We focus on two fields $L$ : the totally ramified extension $\mathbb{Q}_{p}\left(p^{1 / d}\right)$, and the unramified extension of degree $d$, where we take the prime $p$, the degree $d$, and the cutoff $N$ as input parameters.

Fix $a \in\{0,1, \ldots, q-2\}$. First, we compute the matrices $\left(\tau^{(a)}\right)_{0 \leq i \leq j<N /(q-1)}$ following the method discussed in Section A.2.2. Then, for $s=0, \ldots, N /(q-$ 1) -1 , we will appeal to the following result to inductively compute a basis $\left(g_{b}^{(a), s}\right)_{0 \leq b \leq s}$ for the $o_{L}$-span of $\left\{\tau_{i, j}^{(a)}: 0 \leq i \leq j \leq s\right\}$, with each $g_{b}^{(a), s}$ having degree $b$.

Proposition A.3.1. Fix $s \geq 0$, and let $\left(g_{b}^{(a), s-1}\right)_{0 \leq b \leq s-1}$ be a basis for the $o_{L}$-span of $\left\{\tau_{i, j}^{(a)}: 0 \leq i \leq j \leq s-1\right\}$ such that each $\bar{g}_{b}^{(\bar{a}), s-1}$ has degree $b$.

Record the coefficients of these polynomials $g_{*}^{(a), s-1}$ in $s$ row vectors, and append $s+1$ new row vectors obtained from the coefficients of $\tau_{*, s}^{(a)}$ to obtain the $(2 s+1) \times(s+1)$ matrix

$$
B:=\left(\begin{array}{cccc}
Y^{s} & Y^{s-1} & & 1 \\
\bullet & * & \cdots & * \\
& \bullet & \cdots & * \\
& & \ddots & \vdots \\
& & & \bullet \\
* & * & \cdots & * \\
\vdots & \vdots & & \vdots \\
* & * & \cdots & *
\end{array}\right) \underset{g_{s-1}^{(a), s-1}}{(a)}
$$

with coefficients in $L$. The $\bullet$ 's are non-zero (where $B_{s, 0} \neq 0$ because $\sigma_{\underline{s}, \underline{s}}=Y^{\underline{s}}$ by Lemma 4.3.8 which by Equation 19 implies that $\left.\tau_{s, s}^{(a)}=Y^{s}\right)$, so $B$ has rank $s+1$.

Bring the full-rank matrix $B$ to upper-triangular form $B^{\prime}$ using Gaussian elimination over the discrete valuation ring $o_{L}$ as per Lemma A.2.8. Then
(i) we can define the new polynomials $g_{s}^{(a), s}, g_{s-1}^{(a), s}, \ldots, g_{0}^{(a), s}$ by reading off the first $s+1$ rows of $B^{\prime}$, so that each $g_{b}^{(a), s}$ has degree $b$ and $\left(g_{b}^{(a), s}\right)_{0 \leq b \leq s}$ form a basis for the $o_{L}$-span of $\left\{\tau_{i, j}^{(a)}: 0 \leq i \leq j \leq s\right\}$;
(ii) for each $b=0, \ldots, s-1$, the $\pi$-adic valuation of the leading coefficient in the new polynomial $g_{b}^{(a), s}$ is at most that of the old polynomial $g_{b}^{(a), s-1}$.

Proof. By Lemma A. 2.8 the upper-triangular matrix $B^{\prime}$ still has rank $s+1$, so it has only non-zero elements on its main diagonal. Hence for each $b=0,1, \ldots, s$, the polynomial $g_{b}^{(a), s}$ obtained by reading off the $b$-th row has degree $b$. Then of course these polynomials are linearly independent. Also they are the only nonzero rows in $B^{\prime}$, so by Lemma A. 2.7 their $o_{L}$-span is the same as that of the rows of $B$, which by construction is precisely the $o_{L}$-span of $\left\{\tau_{i, j}^{(a)}: 0 \leq 1 \leq j \leq s\right\}$, giving (i).

Now fix $0 \leq b \leq s-1$, and consider what happens to the $b$-th column when we reduce $B$ to $B^{\prime}$. Observe that in the proof of Lemma A.2.8, when we operate on the $j$-th column for $j=0, \ldots, s-b-1$, as the row for $g_{b}^{(a), s-1}$ has a 0 entry in the $j$-th column, it is neither chosen to be the pivot row nor altered as we subtract off multiples of the pivot row. Thus when we operate on the $(s-b)$-th column to determine the $(s-b)$-th row and column of $B^{\prime}$, the leading coefficient of $g_{b}^{(a), s-1}$ must be a candidate for the pivot. But the pivot $B_{s-b, s-b}^{\prime}$ is chosen to have minimal valuation, so $\nu_{\pi}\left(\gamma_{b}\left(g_{b}^{(a), s-1}\right)\right) \geq \nu_{\pi}\left(B_{s-b, s-b}^{\prime}\right)$. Now $B_{s-b, s-b}^{\prime}=\gamma_{b}\left(g_{b}^{(a), s}\right)$ by definition, giving (ii).

For $b$ fixed, it follows that $\nu_{\pi}\left(\gamma_{b}\left(g_{b}^{(a), s}\right)\right), s=b, b+1, \ldots$ is a non-increasing sequence. Moreover, as $g_{b}^{(a), s} \in S^{(a)}$ can be written as an $o_{L}$-linear combination of the $f_{i}^{(a)}$,s and each $f_{i}^{(a)}$ is of degree $i$, we must have $g_{b}^{(a), s}=\sum_{0 \leq i \leq b} \lambda_{i} f_{i}^{(a)}$ for some $\lambda_{i} \in o_{L}$; by looking at the leading coefficient, it follows that

$$
\nu_{\pi}\left(\gamma_{b}\left(g_{b}^{(a), s}\right)\right) \geq \nu_{\pi}\left(\gamma_{b}\left(f_{b}^{(a)}\right)\right) \geq-w_{q}(a+b(q-1))
$$

These observations motivate us to look at the following
Definition A.3.2. For $n=a+b(q-1)$, let $s_{0}(n)$ be the minimal $s \geq b$ such that $\left(g_{b}^{(a), s}\right)_{0 \leq b \leq s}$ satisfies $\nu_{\pi}\left(\gamma_{b}\left(g_{b}^{(a), s}\right)\right)=-w_{q}(n)$, if such $s$ exists; otherwise set $s_{0}(n)=\infty$.

Then whenever $s \geq s_{0}(n)$ in the computations, we can immediately conclude that the equality $\nu_{\pi}\left(\gamma_{b}\left(f_{b}^{(a)}\right)\right)=-w_{q}(a+b(q-1))$ in Lemma A.2.3 holds for this $n=a+b(q-1)$.

We may thus make a small optimisation: at any stage $s$, if $s \geq s_{0}(a+b(q-1))$ for all $0 \leq b<d$ then we can just drop the last $d$ columns when carrying out Gaussian elimination. Indeed for all $s^{\prime}>s$ it is unnecessary to compute $\left(g_{b}^{(a), s^{\prime}}\right)_{0 \leq b<d}$ as the $\pi$-adic valuation of each leading term has already hit the desired minimum, and to compute the leading terms of $\left(g_{b}^{(a), s^{\prime}}\right)_{d \leq b \leq s^{\prime}}$ we do not need the lower-order terms in the last $d$ columns.

Figure 1. extension $=" 3,2,800, \mathrm{ram} "-s_{0}(n)$ in the quadratic ramified extension $\mathbb{Q}_{3}(\sqrt{3})$ for $n<800$. Red points are the $n$ 's for which $s_{0}(n) \geq 800$.
A.4. Data. For reference, the computations in Figure 1 took

- 227.04 seconds for $D$;
- 616.45 seconds for $\tau^{(0)}$ and 616.43 seconds for $\tau^{(1)}$;
- 0.20 seconds for $s=50,1.89$ seconds for $s=100,6.15$ seconds for $s=150,12.09$ seconds for $s=200$, etc. for $a=0$, and slightly less for $a=1$.

We see that $s_{0}(n)-b$ seems to depend on the $p$-adic digits of $n$; we only managed to prove a special case of this pattern, which we will discuss below. Nonetheless, the data do suggest that $s_{0}(n)$ is finite for every $n$ and hence that $\operatorname{Int}\left(o_{L}, o_{L}\right)$ is spanned by the $\sigma_{i, j}$ 's as an $o_{L}$-module.

A similar pattern emerges for larger $p$ and unramified extensions: see Figures 2 and 3 below.

More data and plots can be found at our GitHub repository https:// github.com/Team-Konstantin/Bounded-Functions-on-Character-Varieties/ tree/writeup.

Figure 2. extension $=" 17,2,3216$, ram" $-s_{0}(n)$ in the quadratic ramified extension $\mathbb{Q}_{17}(\sqrt{17})$ for $n<3216$. Note that red points are the $n$ 's for which $s_{0}(n) \geq 3216$ - not enough computation was done to unveil the pattern for the larger $n$ 's!

Figure 3. extension $=" 5,3,12524$, unram" $-s_{0}(n)$ in the cubic unramified extension of $\mathbb{Q}_{5}$ for $n<12524$. Again, note how the red points - the $n$ 's for which $s_{0}(n) \geq 12524$ - give the illusion of $s_{0}(n)-b$ decreasing.

## A.5. Some results.

Definition A.5.1. Given a natural number $n$, let $s_{q}(n)$ be the sum of digits of $n$ in base $q$.

Recall Definition A.3.2:
Definition. For $n=a+b(q-1)$, let $s_{0}(n)$ be the minimal $s \geq b$ such that $\left(g_{b}^{(a), s}\right)_{0 \leq b \leq s}$ satisfies $\nu_{\pi}\left(\gamma_{b}\left(g_{b}^{(a), s}\right)\right)=-w_{q}(n)$, if such $s$ exists; otherwise set $s_{0}(n)=\infty$.

We define the following more intuitive quantity:
Definition A.5.2. For $n=a+b(q-1)$, let $\operatorname{Cap}(n)=a+b s_{0}(n)$. Alternatively, $\operatorname{Cap}(n)$ is the minimal $N \geq n$ such that the $o_{L}$-span of $\left\{\sigma_{i, j}: 0 \leq i \leq j \leq N\right\}$ contains a polynomial of degree $n$ and $\pi$-valuation of the leading term $-w_{q}(n)$.

Here, the equivalence of the two definitions follows from the definition of $s_{0}(n)$.
Let $n=a+b(q-1)$. Analysing the computational results, we are led to believe that, if $s_{q}(n)<p$, then $s_{0}(n)=b$. This is made clear by the following:
Theorem A.5.3. Let $n$ be a positive integer such that $s_{q}(n)<p$. Let $j=n$ and $i=s_{q}(n)$. Then $\sigma_{i, j}$ is a polynomial of degree $n$, with $\pi$-valuation of leading term equal to $-w_{q}(n)$.

Recall the definition of the polynomials $c_{n}(Y)$ from [31]:

$$
[Y](t)=\sum_{n=1}^{\infty} c_{n}(Y) t^{n}
$$

Translating the definition of the polynomials $\sigma_{i, j}(Y)$ and using Lemma 4.3.8, we get:

$$
([Y](t))^{i}=\left(\sum_{n=1}^{\infty} c_{n}(Y) t^{n}\right)^{i}=\sum_{j=i}^{\infty} \sigma_{i, j}(Y) t^{j}
$$

Using the binomial theorem, this gives:

$$
\sigma_{i, j}=\sum_{n_{1}+n_{2}+\ldots+n_{i}=j} c_{n_{1}} c_{n_{2}} \ldots c_{n_{i}}
$$

Of course, for $i=1$ we obtain $\sigma_{1, j}=c_{j}$. So, the proof of the Theorem 3.1 in [31] shows that $\operatorname{Cap}(n)=n$ for $n$ equal to some power of $q$. We will extend this result to all $n$ that have $s_{q}(n)<p$, where $s_{q}(n)$ is the sum of digits of $n$, written in base $q$. For this, we need the following lemma:

Lemma A.5.4. Let $n_{1}, n_{2}, \ldots, n_{i}$ be positive integers. Then, $w_{q}\left(n_{1}\right)+w_{q}\left(n_{2}\right)+$ $\ldots+w_{q}\left(n_{i}\right) \leq w_{q}\left(n_{1}+n_{2}+\ldots+n_{i}\right)$. Equality holds if and only if $s_{q}\left(n_{1}\right)+$ $s_{q}\left(n_{2}\right)+\ldots+s_{q}\left(n_{i}\right)=s_{q}\left(n_{1}+n_{2}+\ldots+n_{i}\right)$, that is, if there is "no carrying" in the sum $n_{1}+n_{2}+\ldots+n_{i}$.

Proof. Direct calculations show that

$$
w_{q}(n)=\frac{n-s_{q}(n)}{q-1}
$$

Substituting into our inequality, we need to prove

$$
s_{q}\left(n_{1}\right)+s_{q}\left(n_{2}\right)+\ldots+s_{q}\left(n_{i}\right) \geq s_{q}\left(n_{1}+n_{2}+\ldots+n_{i}\right)
$$

which can be checked by direct calculations or by induction. Equality holds in the initial inequality if and only if it holds here, which is to say there is "no carrying" in the sum $n_{1}+n_{2}+\ldots+n_{i}$.

Now, we are ready for:
Proof of Theorem A.5.3. Recall that

$$
\sigma_{i, j}=\sum_{n_{1}+n_{2}+\ldots+n_{i}=j} c_{n_{1}} c_{n_{2}} \ldots c_{n_{i}}
$$

where each $c_{k}$ is a polynomial of degree at most $k$, with $\pi$-valuation of the leading term at least $-w_{q}(n)$ (as it is in $\operatorname{Int}\left(o_{L}, o_{L}\right)$ ).

Let's look at each of the terms $c_{n_{1}} c_{n_{2}} \ldots c_{n_{i}}$. As each $c_{k}$ has degree at most $k$, this contributes to the coefficient of $Y^{k}$ in $\sigma_{i, j}$ if and only if $\operatorname{deg}\left(c_{n_{1}}\right)=$ $n_{1}, \operatorname{deg}\left(c_{n_{2}}\right)=n_{2}, \ldots, \operatorname{deg}\left(c_{n_{i}}\right)=n_{i}$. For the moment, assume this is the case. Then, the coefficient of $Y^{n}$ in this product is the product of leading coefficients of the $c_{n_{i}}$ 's, which has $\pi$-valuation at least $-\left(w_{q}\left(n_{1}\right)+w_{q}\left(n_{2}\right)+\ldots+w_{q}\left(n_{i}\right)\right)$. Now, using Lemma A.5.4, this is at least $-w_{q}\left(n_{1}+n_{2}+\ldots+n_{i}\right)=-w_{q}(n)$, with equality if and only if $s_{q}\left(n_{1}\right)+s_{q}\left(n_{2}\right)+\ldots+s_{q}\left(n_{i}\right)=s_{q}(n)=i$, so the $n_{i}$ 's are powers of $q$. That is, the only contribution to the coefficient of $Y^{n}$ in $\sigma_{i, j}$ that has small enough valuation comes from permutations of the unique way of writing $n$ as a sum of $i$ powers of $q$. In other words, if $n=b_{r} b_{r-1} \ldots b_{1} b_{0(q)}$ is the writing of $n$ in base $q$, then the only terms that have a possible contribution are obtained when $\left(n_{1}, n_{2}, \ldots, n_{i}\right)$ is a permutation of $\left(q^{0}, q^{0}, \ldots, q^{1}, \ldots, q^{r}\right)$, where each $q^{k}$ appears $b_{k}$ times.

But, by [31], when $k$ is a power of $q, c_{k}$ is a polynomial of degree exactly $k$, with $\pi$-valuation of leading term exactly $-w_{q}(k)$. So, when $\left(n_{1}, n_{2}, \ldots, n_{i}\right)$ is a permutation as above, the product $c_{n_{1}} c_{n_{2}} \ldots c_{n_{i}}$ is a polynomial of degree $n$, with $\pi$-valuation of leading term equal to $-w_{q}(n)$. Moreover, as proved before, if $\left(n_{1}, n_{2}, \ldots, n_{i}\right)$ is not such a permutation, the product $c_{n_{1}} c_{n_{2}} \ldots c_{n_{i}}$ has the coefficient of $Y^{n}$ either 0 or of $\pi$-valuation larger than $-w_{q}(n)$.

As there are $\binom{i}{b_{0}, b_{1}, \ldots, b_{r}}$ such permutations, with $p \nmid\binom{i}{b_{0}, b_{1}, \ldots, b_{r}}$ (because $i<p$ by the initial assumption on $n$ ), the final sum $\sigma_{i, j}$ has degree $n$, with $\pi$-valuation of leading term $-w_{q}(n)$.

Definition A.5.2 then gives:
Corollary A.5.5. Let $n$ be a positive integer such that $s_{q}(n)<p$. Then $\operatorname{Cap}(n)=n$.

[^0]:    ${ }^{1}$ Note that what Lang calls a formal group should really be called a formal group law.
    ${ }^{2}$ a group object in the category of formal schemes over $\operatorname{Spf} o_{L}$

[^1]:    ${ }^{3}$ Suppose that $\lambda: o_{L} \rightarrow \mathbb{C}_{p}^{\times}$is a locally $L$-analytic character such that $\lambda(1)=1$. Then $\lambda(a)=1$ for all $a \in \mathbb{Z}_{p}$. Hence $\lambda^{\prime}(1)=0$. Since $\lambda$ is locally $L$-analytic, $\lambda^{\prime}$ is $L$-linear, and hence $\lambda^{\prime}=0$ so that $\lambda$ is locally constant, and hence torsion.
