

Notes about the Anderson-Higgs mechanism

I. Electromagnetic wave in a plasma

$$m \frac{d\vec{v}}{dt} = q\vec{E} \Rightarrow \frac{d\vec{v}}{dt} = \frac{q^2}{m} \vec{E} \quad \equiv \omega_p^2$$

$$\vec{\nabla}(\underbrace{\vec{\nabla} \cdot \vec{E}}_0) - \Delta \vec{E} = \vec{\nabla} \times (\vec{\nabla} \times \vec{E}) = -\frac{\partial}{\partial t} (\vec{\nabla} \times \vec{B}) = -\frac{\partial}{\partial t} \left(\vec{1} + \frac{\partial \vec{E}}{\partial t} \right) = -\left(\frac{q^2}{m} + \frac{\partial^2}{\partial t^2} \right) \vec{E}$$

→ KG equation, dispersion $\omega^2 = k^2 + \omega_p^2$.

→ The photon in a plasma is massive.

II. Equivalence mass $\leftrightarrow$ length scale

Understand the photon mass as a typical length scale (beyond just dim. analysis).

Coulomb interaction between charged particles: 

The Coulomb force as the susceptibility:

$$\chi(\omega=0, \vec{q}) = \underbrace{\vec{q}}_{\text{wavy line}} = \frac{1}{q^2 + \omega_p^2} \quad \xrightarrow{FT, d=3} \chi(r) = \frac{e^{-\omega_p r}}{r}$$

Massless case ($\omega_p=0$) recovers Coulomb in the vacuum, while the massive case ($\omega_p>0$) describes screened interaction.

III. Link to Debye (or Thomas-Fermi) screening

$$\left\{ \begin{array}{l} \rho(r) = -\nabla^2 V(r) \\ \rho(r) = +Q \delta(r) + \sum_i \rho_0^i \exp\left(-\frac{q_i V(r)}{k_B T}\right) \end{array} \right. \quad = \sum_i \rho_0^i q_i / k_B T$$

$$\Rightarrow \nabla^2 V(r) \simeq -Q \delta(r) - \underbrace{\sum_i \rho_0^i}_{\text{neutral electrolyte}} \left(1 - \frac{q_i V(r)}{k_B T}\right) = -Q \delta(r) + \lambda_D^{-2} V(r)$$

Solution: $V(r) = \frac{Q}{4\pi r} e^{-r/\lambda_D} \rightarrow \text{identify } \omega_p \equiv \lambda_D^{-1}$

⇒ EM in a charged medium is screened i.e. massive.

IV. This is the physics of superconductors

1) Justification:

The KG equation appears because $\frac{d\vec{J}}{dt} \propto \vec{E}$, i.e. $\sigma(\omega) \sim \frac{1}{j\omega}$.

This is the SC limit of the Drude conductivity $\sigma(\omega) = \frac{\sigma_0}{j\omega + 1/\tau}$ ($\tau \rightarrow \infty$).

(cf note about transport for more details).

in other words $\vec{J} \sim \vec{A}$

2) Ginzburg-Landau for a charged field

• Neutral GL free energy: $\mathcal{L}_{GL} = \frac{1}{2m} |\nabla\psi|^2 + r|\psi|^2 + \frac{u}{2} |\psi|^4$

Rewrite $\psi = |\psi| e^{i\phi} \Rightarrow \mathcal{L}_{GL} = \underbrace{\frac{|\psi|^2}{2m} (\nabla\phi)^2}_{\text{phase stiffness in the ordered phase}} + \left[\frac{1}{2m} (\nabla|\psi|)^2 + r|\psi|^2 + \frac{u}{2} |\psi|^4 \right]$

• Charged case: now gauge invariance $\psi \rightarrow e^{i\alpha} \psi$, $\vec{A} \rightarrow \vec{A} + \frac{1}{q} \vec{\nabla}\alpha$.

$$\mathcal{L}[\psi, \vec{A}] = \frac{1}{2m} |(\vec{\nabla} - iq\vec{A})\psi|^2 + r|\psi|^2 + \frac{u}{2} |\psi|^4 + \frac{1}{2\mu_0} |\vec{\nabla} \times \vec{A}|^2$$

Equations of motion: $\vec{\nabla} \times \vec{B} = \mu_0 \vec{J}$ and non-linear Schrödinger.

$$\underbrace{\mu_0 |\psi|^2 q^2 / m}_{\text{phase stiffness}} \hookrightarrow \mathcal{L} = \frac{-iq}{2m} (\psi^* \vec{\nabla} \psi - \psi \vec{\nabla} \psi^*) - \underbrace{\frac{q^2}{m} |\psi|^2 \vec{A}}_{\text{this term appears in the ordered phase}} \quad \text{!}$$

and ultimately $\nabla^2 \vec{B} = \lambda_L^{-2} \vec{B}$

this term appears in the ordered phase.

$\hookrightarrow$ the Meissner effect $\sim$ Debye screening $\sim$

3) Slightly more formally

Action of a charged superfluid in the ordered phase $\psi(\vec{r}, t) = m_s e^{i\phi(\vec{r}, t)}$:

require gauge invariance $\phi \rightarrow \phi + \alpha(\vec{r}, t)$; $\vec{A} \rightarrow \vec{A} + \frac{1}{q} \vec{\nabla}\alpha$; $\psi \rightarrow \psi - \frac{1}{q} \partial_t \alpha$.

$$\text{then } S = \int dt d^3\vec{r} \frac{m_s}{2m} \left[(\dot{\phi} + q\psi)^2 - (\vec{\nabla}\phi - q\vec{A})^2 \right] + \frac{1}{2\mu_0} [\vec{E}^2 - \vec{B}^2]$$

Now idea: absorb all fluctuations $\dot{\phi}$, $\vec{\nabla}\phi$ into $(\varphi, \vec{A})$. (does not change $\vec{E}, \vec{B}$)

$$\Rightarrow S = \int dt d^3\vec{r} \left\{ \frac{m_s q^2}{2m} (\varphi^2 - \vec{A}^2) + \frac{1}{2\mu_0} [\vec{E}^2 - \vec{B}^2] \right\}$$

$\hookrightarrow$ now mass terms for φ and $\vec{A}$! this is Anderson-Higgs.

V. Really more formally (but nothing really new)

Here I want to give the "full" picture, including condensation.

$$\mathcal{L} = (\partial^\mu \Psi^\dagger - iq A^\mu \Psi^\dagger)(\partial_\mu \Psi + iq A_\mu \Psi) + \mu^2 \Psi^\dagger \Psi - \lambda (\Psi^\dagger \Psi)^2 - \frac{1}{4} F_{\mu\nu} F^{\mu\nu}.$$

Gauge symmetry $\begin{cases} \Psi \rightarrow e^{i\alpha(x)} \Psi \\ A_\mu \rightarrow A_\mu - \frac{1}{q} \partial_\mu \alpha(x) \end{cases}$ (NB: can be generalized to nonabelian)

Write $\Psi(x) = \rho(x) e^{i\theta(x)}$ and replace $A_\mu + \frac{1}{q} \partial_\mu \theta =: C_\mu$

$$\Rightarrow \mathcal{L} = (\partial_\mu \rho)^2 + \rho^2 q^2 C_\mu C^\mu + \mu^2 \rho^2 - \lambda \rho^4 - \frac{1}{4} F_{\mu\nu} F^{\mu\nu}$$

In the SB manifold $\rho_0 = \sqrt{\mu^2/\lambda}$, and spontaneously chosen $\theta = 0$:
($\rho = \rho_0 + \chi$)

$$\mathcal{L}_{\text{SB}} = \frac{1}{2} (\partial_\mu \chi)^2 - \mu^2 \chi^2 - \frac{1}{4} F_{\mu\nu} F^{\mu\nu} + \underbrace{\frac{q^2 \mu^2}{2\lambda} C_\mu C^\mu}_{\text{mass term for the gauge field}} + \dots$$

$\rightarrow$ mass term for the gauge field.

VI. Remark: counting degrees of freedom

1) The photon polarizations

The photon has spin $S=1$ so in principle $S^2 = +1, 0, -1$.

Answer: first consider massive EM, $\mathcal{L} = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} + \frac{m^2}{2} A_\mu A^\mu$

then there is 1 constraint, $\partial_\mu A^\mu = 0$, whence 3 copies of the KG equation.

Now massless: since $m^2 A_\mu A^\mu$ is no longer there to break gauge invariance, one can fix the gauge to remove one additional d.o.f, whence, 2 polarizations.

2) Before/after Anderson-Higgs

$$\begin{cases} 2 \text{ massive scalars } \Psi^\dagger, \Psi \\ \text{massless photon: 2 polarizations} \end{cases} \xrightarrow{\text{AH}} \begin{cases} 1 \text{ massive scalar } \chi \\ \text{massive photon: 3 polarizations} \end{cases}$$

$\rightarrow$ the composite object $C_\mu = A_\mu + \frac{1}{q} \partial_\mu \theta$ as the new massive photon.

VII. This is not the same as confinement!

True: in both cases, field lines become costly and there is a mass generated for the gauge field. But:

↳ Consequences for two test charges and the field lines:

screening

confinement

↳ Confinement occurs for pure gauge theories (cf Polyakov '77 for $U(1)$ e.g. from the proliferation of instantons (which are pure g.t.).

≠ Screening from Anderson-Higgs arises from interaction w/ matter.
(well, at least in the abelian case, see later)

VIII. Reminder about gauge theories.

• Assume we have a theory of fermions f_r, b_r , with Lagrangian $\mathcal{L}_f$, and we want to enforce the constraint $\sum_{\alpha=1} b_{r\alpha}^\dagger b_{r\alpha} = 1 \quad \forall r, \forall t$.

⇒ Lagrange multiplier: $\mathcal{L}_{\text{tot}} = \mathcal{L}_f - a_0(r,t) \left[\sum_{\alpha} b_{r\alpha}^\dagger b_{r\alpha} - 1 \right]$

Indeed $\int [D a_0(r,t)] e^{-\int \mathcal{L}_{\text{tot}} dt} \propto \prod_{r,t} \delta \left(\sum_{\alpha} b_{r\alpha}^\dagger b_{r\alpha} - 1 \right)$

→ The "dynamical potential" $a_0(r,t)$ enforces the constraint $\forall r, t$!
Now what does this have to do with a gauge theory?

• In $\mathcal{L}_f$, the term $J_{ij} b_{i\alpha}^\dagger b_{j\alpha} e^{-i a_{ij}}$ (i, j = positions, α = "spin") is invariant under $b_{i\alpha}^\dagger \rightarrow b_{i\alpha}^\dagger e^{i\theta_i}$ provided that $a_{ij} \rightarrow a_{ij} + \theta_i - \theta_j$.

This is a $U(1)$ gauge theory all right.

Now look at a given state $b_{1,1}^\dagger b_{2,1}^\dagger b_{2,2}^\dagger b_{3,1}^\dagger \dots b_{N-1,1}^\dagger b_{N-1,2}^\dagger b_{N,1}^\dagger |0\rangle$.

Which phase does it pick up under such a gauge transformation?

Answer: $\prod_i \exp(i\theta_i [Q_i + 1])$ where $Q_i = \sum_{\alpha} b_{i\alpha}^\dagger b_{i\alpha} - 1$.

in other words: the local charge generates gauge transformations.

IX - Parton constructions, from $SU(2)$ to $U(1)$

- Representation of spins using Abrikosov fermions:

$$\vec{S}_r = \frac{1}{2} \underbrace{f_{r\alpha}^\dagger \vec{\sigma}_{\alpha\beta} f_{r\beta}}_{\text{recovers the spin algebra}} \quad \text{and constraint} \quad \underbrace{\sum_{\alpha=\uparrow,\downarrow} f_{r\alpha}^\dagger f_{r\alpha}}_{\text{recovers the } S=\frac{1}{2} \text{ Hilbert space}} = 1 \quad \forall r.$$

Redundancy in this description: $f_\uparrow^\dagger$ and $f_\downarrow$ mean the same thing.

→ Doublet $\Psi = \begin{pmatrix} f_\uparrow^\dagger \\ f_\downarrow^\dagger \end{pmatrix}$. Idea: $\alpha f_\uparrow^\dagger + \beta f_\downarrow^\dagger$ works as well.

i.e.: acting on Ψ with an $SU(2)$ matrix preserves $\vec{S}_r$.

→ Gauge symmetry of the parton construction.

- Usually perform some sort of mean-field, with param $\underline{U}_{ij}$ ^{$\leftarrow 2 \times 2$} , and $H_{MF} = \sum_{\langle ij \rangle} J_{ij} (\Psi_i^\dagger \underbrace{\underline{U}_{ij}}_{\in SU(2)} e^{i a_j^\ell \tau^\ell} \Psi_j + h.c.) + a_j^\ell \Psi_i^\dagger \tau^\ell \Psi_j$.

This is a theory of fermions coupled to an $SU(2)$ gauge field. Now, usually we don't have this but just $U(1)$. How come?

- Possible answer to the above: the $SU(2)$ g.f. has become massive except for one $U(1)$ subgroup of it.
But is it possible to do Anderson-Higgs without a condensate?

- Idea: recall gauge charges are generators of g.t.

Indeed they do not commute trivially with the gauge field e^{iA} , and in the abelian case they alone have this property.

But in the nonabelian case, " e^{iA} " itself has nontrivial commutation rules with itself!

→ In the nonabelian case, there can be Anderson-Higgs without a condensate since different components of the gauge group are charged objects for each other!

X. Anderson-Higgs of pure $su(2)$

- By definition, energy is gauge-invariant: $E[\{U_{ij}\}] = E[\{W_i U_{ij} W_j^\dagger\}]$

Question: are mass terms $\propto (A_{ij}^l)^2$ allowed by gauge invariance?

To answer it, consider $P_{C_i} = \bar{U}_{ij} \bar{U}_{jk} \dots \bar{U}_{li}$ 

And $P_{C_i} = \chi_{C_i}^0 \tau^0 + i \chi_{C_i}^l \tau^l$ is charged: $P_{C_i} \rightarrow W_i P_{C_i} W_i^\dagger$

- Now consider the effect of g.t. $e^{i A_{ij}^l \tau^l} \rightarrow e^{i \theta_i^l \tau^l} e^{i A_{ij}^l \tau^l} e^{-i \theta_j^l \tau^l}$

$\Rightarrow$ Several phases depending on the flux of our MF ansatz $\bar{U}_{ij}$.

$\hookrightarrow$ Trivial flux $P_{C_i} \propto \tau^0$. (and $\bar{U}_{ij} \propto \tau^0$ up to free g.t.)

Then $su(2)$ is preserved, and $A_{ij}^l \rightarrow A_{ij}^l + \theta_i^l - \theta_j^l$ (at least) $\forall l=1,2,3$

so the mass term $(A_{ij}^l)^2$ is not allowed. $\forall l=1,2,3$. $\hookrightarrow$ we could mix them

$\hookrightarrow$ Collinear flux: say $\bar{U}_{ij} = i e^{i \varphi_{ij} \tau^3}$ and $P_{C_i} = \chi_{C_i}^0 \tau^0 + \chi_{C_i}^3 \tau^3$

Then $su(2)$ is broken down to $u(1)$ and $A_{ij}^3 \rightarrow A_{ij}^3 + \theta_i^3 - \theta_j^3$

is the only remaining gauge invariance. So $(A_{ij}^3)^2$ is not allowed,

but the two other degrees of freedom $A_{ij}^{1,2}$ are now gapped!

$\hookrightarrow$ Noncollinear: then all bosons are gapped $\rightarrow$ discrete g.t. (?)

- NB: above we have just said that the $(A_{ij}^3)^2$ term is not allowed, while no such statement could be made about $(A_{ij}^{1,2})^2$.

Can we be more explicit and show a mass term for $A_{ij}^{1,2}$?

$\Leftrightarrow$ a term invariant under $su(2)$ whose quadratic order is $\sim (A_{ij}^{1,2})^2$.

$\hookrightarrow$ It turns out that $E = \kappa \text{Tr} [P_{C_i} \bar{U}_{i,i+x} P_{C_{i+x}} \bar{U}_{i+x,i}]$ works.

At quadratic order, $E = \frac{\kappa}{2} (-\chi^2) \text{Tr} ([P_{C_i}, A_x^l \tau^l]^2) + \dots$ $\rightarrow \chi e^{i \phi_x \tau^3} = \bar{U}_{ij}$

$\hookrightarrow$ if $\propto (\tau^0, \tau^3)$ then $E \sim (A_x^{1,2})^2$.

XI - An "application": the Peierls mechanism ^{→ disputable!} → polyacetylene.

Basically a 1d molecule with right-movers, left-movers, and the hopping amplitude depends on the distance. elastic energy $\propto \Delta(x)^2$.

→ Role of staggered displacement $\Delta_m = (-1)^m u_m \rightarrow \Delta(x)$.

$$\left[\mathcal{L} = i\psi^\dagger (\partial_t + v_F \partial_x \hat{\sigma}^2) \psi - \frac{1}{2} \Delta^2 - \alpha \Delta(x) \psi^\dagger \hat{\sigma}^x \psi \right] \psi = \begin{pmatrix} \psi_R \\ \psi_L \end{pmatrix}$$

Now if we give a U(1) charge +1 to R and -1 to L,

we see that $\Delta(x)$ is a charge-2 field. (NB this is not the usual way to see it).

And it turns out that $\Delta(x)$ condenses $\rightarrow \bar{\Delta}$. (integrate out the ψ s etc).

Consequence of "Anderson-Higgs": the "gauge field" (here, the fermions) acquires a mass $\rightarrow$ Here it means $H = i v_F \psi^\dagger \partial_x \hat{\sigma}^2 \psi + \underbrace{\alpha \bar{\Delta} \psi^\dagger \hat{\sigma}^x \psi}_{\text{mass term}}$.

XII - Another application: heavy fermions

Basic idea: local moments $\uparrow \downarrow$ interact with itinerant $\bar{e}$ s $\uparrow \downarrow$ to form mobile (but heavy) fermions $\uparrow \downarrow$.
 $\hookrightarrow$ enlarged FS (cf talk about Luttinger's theorem).

Declare $\uparrow = f^\dagger \bar{\sigma} f$ and $\downarrow = c^\dagger \bar{\sigma} c$. There are 2 fermion species.

The $c^\dagger$ fermions are charged under usual EM: $c^\dagger \rightarrow c^\dagger e^{-i\alpha}$, $A_\mu \rightarrow A_\mu + (\vec{\nabla}\alpha) \frac{1}{e}$.

The $f^\dagger$ fermions, under an emergent EM: $f^\dagger \rightarrow f^\dagger e^{-i\chi}$, $A_\mu \rightarrow A_\mu + \vec{\nabla}\chi$.
 (because their number is fixed)

Condensation of the hybridization $V = \langle f^\dagger c \rangle$ charged under $\begin{cases} \vec{A} \rightarrow e\vec{A} \\ \lambda \rightarrow e\Phi \end{cases}$ i.e. $A_\mu \rightarrow e A_\mu$.
 $\rightarrow$ the latter becomes massive!

The action for Φ , the phase of the hybridization V , is now:

$$S_{\text{eff}} = \int d^3x dt \left\{ \frac{\rho_F}{2} (\vec{\nabla}\Phi - \vec{A} + e\vec{A})^2 - \frac{\chi_F}{2} (i\partial_t \Phi + \lambda - e\Phi)^2 \right\}.$$

The "Meissner effect" here is: $\begin{cases} \vec{A} = e\vec{A} \\ \lambda = e\Phi \end{cases} \rightarrow$ the 2 g.f.s are locked together.

$\Rightarrow$ The f fermions have become charged under usual EM.
 Besides, there is now only 1 surviving U(1) gauge theory.
 And all the fermions are charged under it $\rightarrow$ enlarged FS.
