## **TD 6: Message Authentication Codes**

Exercise 1. Insecure MACs

Let  $F: \{0,1\}^t \times \{0,1\}^n \to \{0,1\}^n$  be a secure pseudo-random function (PRF). Show that each one of the following message authentication codes (MAC) is insecure:

- **1.** To authenticate  $m = m_1 \| \dots \| m_d$  where  $m_i \in \{0,1\}^n$  for all i, compute  $t = F(k, m_1) \oplus \dots \oplus F(k, m_d)$ .
- **2.** To authenticate  $m = m_1 \parallel \ldots \parallel m_d$  with  $d < 2^{n/2}$  and  $m_i \in \{0,1\}^{n/2}$  for all i, compute

$$t = F(k, 1 \parallel m_1) \oplus \ldots \oplus F(k, d \parallel m_d),$$

where *i* is an n/2-bit long representation of *i*, for all  $i \le d$ .

Exercise 2. CCA Insecurity

Let us consider the following symmetric encryption scheme, where  $F: \{0,1\}^s \times \{0,1\}^n \to \{0,1\}^\ell$  is a secure PRF. To encrypt a message  $m \in \{0,1\}^\ell$  for  $\ell \in \mathbb{N}$ :

**KeyGen**( $1^{\lambda}$ ): Output  $k \leftarrow U(\{0,1\}^s)$ .

**Enc**(k, m): Sample  $r \leftarrow U(\{0,1\}^n)$  and output  $c := (r, F(k, r) \oplus m)$ .

**Dec**( $k, c := (c_1, c_2)$ ): Output  $m = c_2 \oplus F(k, c_1)$ .

- 1. Recall the security definition of the CCA-security of an encryption scheme.
- 2. Is this scheme CCA-secure?

Exercise 3. CBC-MAC

Let  $F: \{0,1\}^k \times \{0,1\}^n \to \{0,1\}^n$  be a PRF, d > 0 and L = nd. Prove that the following modifications of CBC-MAC (recalled in Figure 1) do not yield a secure fixed-length MAC. Define  $t_i := F(K, t_{i-1} \oplus m_i)$  for  $i \in [1,d]$  and  $t_0 := IV = 0$ .

**1.** Modify CBC-MAC so that a random  $IV \leftarrow U(\{0,1\}^n)$  (rather than  $IV = \mathbf{0}$ ) is used each time a tag is computed, and the output is  $(IV, t_d)$  instead of  $t_d$  alone.

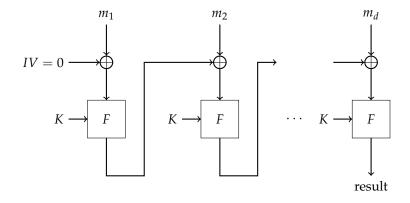

Figure 1: CBC-MAC

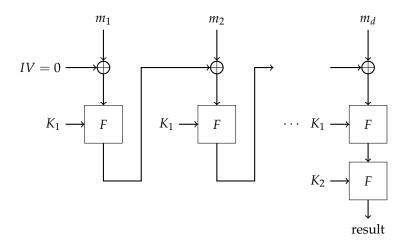

Figure 2: ECBC-MAC

**2.** Modify CBC-MAC so that all the outputs of *F* are output, rather than just the last one.

We now consider the following ECBC-MAC scheme: let  $F: K \times X \to X$  be a PRF, we define  $F_{ECBC}: K^2 \times X^{\leq L} \to X$  as in Figure 2, where  $K_1$  and  $K_2$  are two independent keys. If the message length is not a multiple of the block length n, we add a pad to the last block: m =

If the message length is not a multiple of the block length n, we add a pad to the last block:  $m = m_1 | \dots | m_{d-1} | (m_d || pad(m))$ .

3. Show that there exists a padding for which this scheme is not secure.

For the security of the scheme, the padding must be invertible, and in particular for any message  $m_0 \neq m_1$  we need to have  $m_0 || \operatorname{pad}(m_0) \neq m_1 || \operatorname{pad}(m_1)$ . In practice, the ISO norm is to pad with  $10 \cdots 0$ , and if the message length is a multiple of the block length, to add a new "dummy" block  $10 \cdots 0$  of length n.

**4.** Prove that this scheme is not secure if the padding does not add a new "dummy" block if the message length is a multiple of the block length.

*Remark:* The NIST standard is called CMAC, it is a variant of CBC-MAC with three keys  $(k, k_1, k_2)$ . If the message length is not a multiple of the block length, then we append the ISO padding to it and then we also XOR this last block with the key  $k_1$ . If the message length is a multiple of the block length, then we XOR this last block with the key  $k_2$ . After that, we perform a last encryption with F(k,.) to obtain the tag.
